ACIP CMV Vaccine Workgroup
Cytomegalovirus (CMV) and congenital CMV (cCMV) Epidemiology and Disease Burden

Tatiana M. Lanzieri, MD, MPH
ACIP CMV WG Co-Lead

April 15th, 2025

Measles, Rubella and CMV Epidemiology Team
Viral Vaccine Preventable Diseases Branch
Division of Viral Diseases

Objectives

- Review epidemiology and disease burden of CMV and cCMV

More than 16,000 children born with cCMV infection in the U.S. every year – 4.5 per 1,000 live births

Outcome	Annual number of affected children	%
Neonatal death	80	0.5
cCMV disease†	2800	17
Long-term outcomes *(selected)*		
Sensorineural hearing loss	825	5
Cognitive impairment	495	3
Motor impairment	165	1

Frequencies based on unpublished review of 30 unique cohorts of children with cCMV identified through newborn screening followed up through childhood.

cCMV disease

Neonatal signs

- Rash (purpura/petechiae)
- Enlarged liver and/or spleen (hepatosplenomegaly)
- Small head (microcephaly)

Laboratory diagnosis

- PCR or culture positive on urine, blood, cerebrospinal fluid collected within 21 days of life

Most newborns with cCMV infection have no clinical signs at birth and are not diagnosed

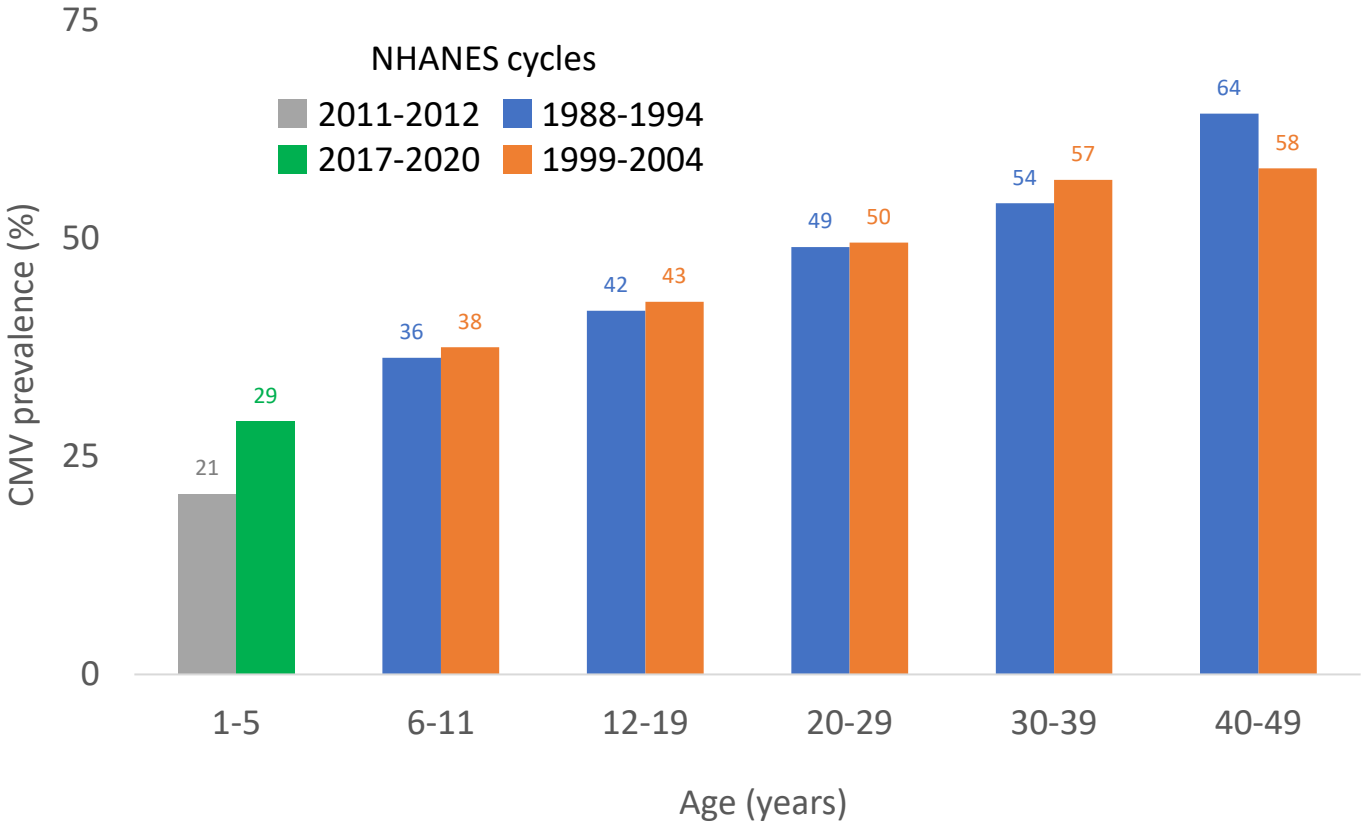
CMV IgG Seroprevalence, United States

National Health and Nutrition Examination Surveys (NHANES)



- **Increase with older age**
- **Persons 6-49 years:**
  - No significant changes from 1988-1994 to 1999-2004
- **Children 1-5 years:**
  - Increased from 21% to 29% between 2011-2012 and 2017-2020 pre-pandemic

Risk of vertical transmission and cCMV disease according to timing and type of maternal infection

	Transmission rate (%)	Symptomatic at birth* (%)	SNHL or neurodevelopmental abnormality* (%)
Primary infection†			
Periconception	21.0	1.3	-
First trimester	36.8	9.1	22.8
Second trimester	40.3	0.3	0.1
Third trimester	66.2	0.4	0.0
Non-primary infection	3.4§	3 of 7§§	3 of 7§§

†Primary maternal infection in CMV-seronegative women was defined as seroconversion or low avidity IgG; pooled rates of vertical transmission following primary maternal infection from 10 studies, 2942 fetuses
*Pooled rates of cCMV disease from 10 studies, 796 infected fetuses
§ Transmission rate from 1 study including 205 pregnant women diagnosed with non-primary infection
§§ Sample too small, 6 in the first trimester and 1 unknown timing

Chatzakis et al. Timing of primary maternal cytomegalovirus infection and rates of vertical transmission and fetal consequences. AJOG 2020
Simonazzi et al. Perinatal outcomes of non-primary maternal CMV infection: a 15-year experience. Fetal Diagn Ther 2017.

Risk of vertical transmission and cCMV disease according to timing and type of maternal infection

	Transmission rate (%)	Symptomatic at birth* (%)	SNHL or neurodevelopmental abnormality* (%)
Primary infection†			
Periconception	21.0	1.3	-
First trimester	36.8	9.1	22.8
Second trimester	40.3	0.3	0.1
Third trimester	66.2	0.4	0.0
Non-primary infection	3.4§	3 of 7§§	3 of 7§§

†Primary maternal infection in CMV-seronegative women was defined as seroconversion or low avidity IgG; pooled rates of vertical transmission following primary maternal infection from 10 studies, 2942 fetuses
*Pooled rates of cCMV disease from 10 studies, 796 infected fetuses

Incidence of CMV primary infection and reinfection varies across populations

Country	Annual rate		Population (Assessment)
	Primary (PI) IgG seroconversion	Reinfection (R) IgG seroconversion to new CMV strains	
US	**0.4-7%**	**10%**	PI: pregnant women, IgG seroconversion, low IgG avidity or viral shedding in clinical trials and other studies [1,2,3,4] R: post-partum women, IgG seropositive with seroconversion to new strains [5]
Brazil	**20%**	**9-35%**	Pregnant women, IgG seronegative during 1st trimester or seropositive at first prenatal visit [6,7] R: range for non-transmitters vs. transmitters mothers

Proportions of cCMV infections due to non-primary maternal infection (NPI) vary with maternal seroprevalence but risk of cCMV infection is higher when mother is CMV seronegative before pregnancy

Country, years (n° infants screened)	Maternal CMV IgG seroprevalence	cCMV infection prevalence per 1,000 live births	Risk of cCMV among seronegative vs. seropositive mother	Proportion attributable to NPI
France, 2013-2015 (12,000)	61%	3.7	0.86% vs. 0.2% (4x)	52%
Brazil, 2013-2017 (12,000)	97%	5.7	2.8% vs. 0.5% (6x)	90%

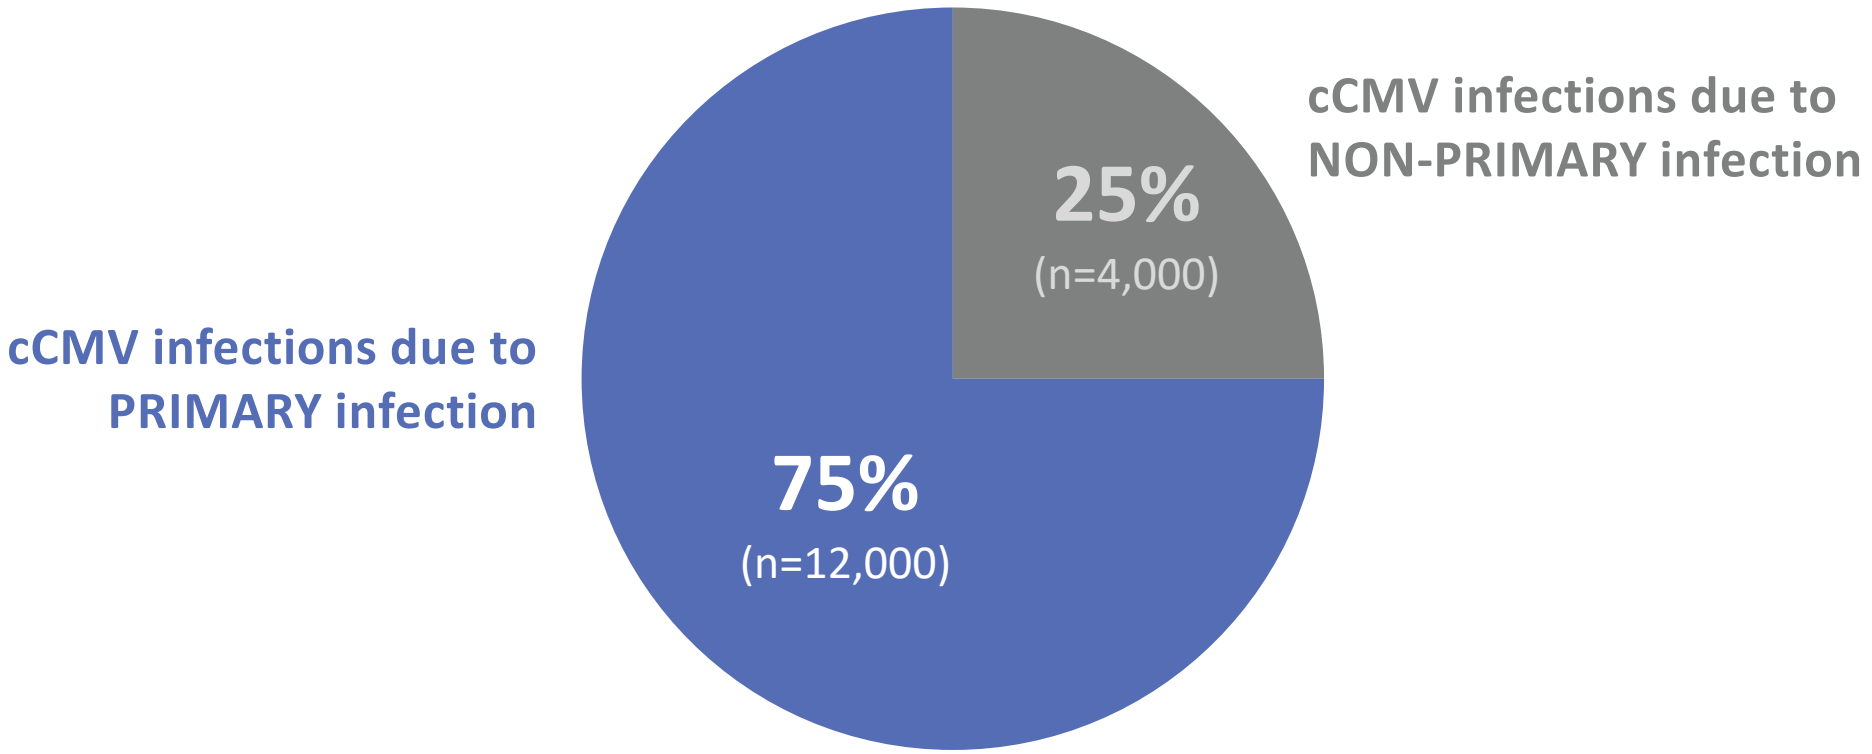
Mussi-Pinhata et al. Seroconversion for Cytomegalovirus Infection During Pregnancy and Fetal Infection in a Highly Seropositive Population: "The BraCHS Study". JID 2018

About 12,000 cCMV infections in the U.S. every year may be attributable to primary maternal infections*



* Using 3,667,758 live births in US 2022 NVSS - Birth Data (cdc.gov), stratified by maternal age group and birth order
Unpublished estimates based on CMV seroprevalence data from NHANES; other studies 25-50% cCMV infections attributed to primary maternal infections.

Young children play a critical role in CMV transmission

- **Children with CMV infection excrete large amounts of virus in saliva and urine for months**

- **CMV excretion peaks at 1-2 years of age**
  - 1/3 of first-time mothers will be pregnant again, with a second birth within <18 months of the first
  - More likely with day care attendance (2x)
  - Higher risk of cCMV in second-born children

Modeling suggest that short-duration of protection in infants can impact transmission to pregnant mothers and decrease cCMV infections

Model	Population	Vaccine efficacy (%)	Duration of protection (years)	Vaccine coverage (%)	Effect 50 years post-vaccination
Byrne*	2m	35	1	67	85% ↓cCMV infections
Lanzieri§	<1y	60	5	50	Elimination
	12-18m and 15-19y	70	5	60	30% ↓cCMV infections
	20-29y	60	5	50	10% ↓cCMV infections
Alfaro-Murillo†	19-20y (CMV neg. F)	95	25	90	4% ↓cCMV disease
	<1y (CMV neg. F)	95	4	90	2% ↓cCMV disease

*Protection estimated for primary infection (35% for up to 1 year)
†Screening coverage, all CMV-seronegative vaccinated
§Potential for increase in congenital CMV infections due to primary maternal infections predicted in high seroprevalence settings (Brazil) without booster at 15-19y

Models predict different impact of vaccine in US

Model	Population	Vaccine efficacy (%)	Duration of protection (years)	Vaccine coverage (%)	Effect 50 years post-vaccination
Byrne*	2m	35	1	67	85% ↓cCMV infections
Lanzieri§	<1y	60	5	50	Elimination
	12-18m and 15-19y	70	5	60	30% ↓cCMV infections
	20-29y	60	5	50	10% ↓cCMV infections
Alfaro-Murillo†	19-20y (CMV neg. F)	95	25	90	4% ↓cCMV disease
	<1y (CMV neg. F)	95	4	90	2% ↓cCMV disease

*Protection estimated for primary infection (35% for up to 1 year)
†Screening coverage, all CMV-seronegative vaccinated
§Potential for increase in congenital CMV infections due to primary maternal infections predicted in high seroprevalence settings (Brazil) without booster at 15-19y

Summary

- **The epidemiology of CMV and cCMV is complex**
- **In the United States, nearly 75% of cCMV infections due to primary maternal infection**
  - Globally, most cCMV infections due to non-primary maternal infection
- **An effective CMV vaccine could reduce cCMV disease burden**
  - Long-lasting immunity to ensure women are protected *before pregnancy* and *throughout childbearing years*
  - Vaccination of toddlers could provide *indirect protection* to pregnant women
