## Human Anthrax Associated With an Epizootic Among Livestock — North Dakota, 2000

On August 28, 2000, the North Dakota Department of Health was notified by a local clinician of a patient with a cutaneous lesion suggestive of anthrax following exposure to an infected animal carcass. This report summarizes the investigation of this case, which was associated with an anthrax epizootic among livestock in North Dakota, and emphasizes the importance of increased vigilance for human cases of anthrax during and following outbreaks of anthrax among livestock.

On August 19, 2000, a 67-year-old resident of eastern North Dakota participated in the disposal of five cows that had died of anthrax. On the day of disposal, he placed chains around the heads and hooves of the animals and moved them to a burial site. He reported having worn leather gloves throughout transportation and disposal.

On August 23, he noticed a small bump on his left cheek at the angle of his jaw. On August 25, the lesion had enlarged and he sought medical attention. He denied fever, malaise, headache, pruritus, or difficulty swallowing. On examination, the lesion was indurated to approximately the size of a quarter and was surrounded by a purple colored ring. The patient was afebrile and did not appear ill. The physician reported a firm, nontender, superficial nodule with an overlying 0.5 cm black eschar. No drainage was noted and neither wound nor blood cultures was obtained. The patient was placed on ciprofloxacin 500 mg twice a day for presumed cutaneous anthrax.

On follow-up examination on August 28, the eschar had enlarged to 1 cm. Following consultation with the North Dakota Department of Health and based on clinical suspicion of anthrax, the patient continued the course of ciprofloxacin for a total of 14 days. The lesion slowly improved over several weeks. Paired serum specimens were obtained on September 22 and October 5, 2000, and were tested at CDC; both had positive antibody titers by ELISA of 200 to protective antigen, confirming infection with *Bacillus anthracis*.

This case was associated with an anthrax epizootic in North Dakota, during which 32 farms were quarantined for anthrax in 2000\*, compared with an average of two farms per year during the preceding 40 years (Figure 1). The initial cases were detected in May 2000, when four animals were found dead on a farm; the deaths were later confirmed to be associated with anthrax. During the epizootic, which extended from July 6 through September 24, 2000, 157 animals died on 31 farms on which 62 persons were involved with animal care, vaccination, specimen processing, or carcass disposal. No other cases of symptomatic anthrax were identified in humans in North Dakota.

<sup>\*</sup>A quarantined farm is one on which at least one case of culture-confirmed anthrax has occurred among livestock.

Human Anthrax — Continued

FIGURE 1. Number of farms quarantined for anthrax — North Dakota, 1962–2000

Meningitis and Special Pathogens Br, Div of Bacterial and Mycotic Diseases, National Center for Infectious Diseases; and an EIS Officer, CDC.

**Editorial Note**: This report presents the first case of cutaneous anthrax in the United States since 1992. In the United States, the annual incidence of human anthrax declined from approximately 200 cases in the early 1900s to no human cases since 1992. Although most cases reported in the United States have been cutaneous, 18 cases of inhalational anthrax were reported during the 20th century, most recently in 1976 (1). No cases of gastrointestinal anthrax have been reported in the United States.

Anthrax most commonly occurs in both wild and domestic mammals (e.g., cattle, sheep, goats, camels, antelopes, and other herbivores) (2). Humans develop anthrax infection following exposure to infected animals, tissue from infected animals, or by direct exposure to *B. anthracis* (3,4). Exposure to infected animal tissue can occur during postmortem examination, slaughter, or handling of infected meat or hides. Exposure also can occur during laboratory manipulation of infected blood, muscle, or other tissues. Human-to-human transmission of anthrax is rare.

Anthrax can occur in three forms: cutaneous, gastrointestinal, and inhalational (2). Most cases (95% worldwide) are cutaneous. The incubation period for cutaneous anthrax ranges from 12 hours to 12 days (2–5). Cutaneous anthrax may begin with pruritus at the affected site, typically followed by a small, painless papule that progresses to a vesicle in 1–2 days. The lesion erodes, leaving a necrotic ulcer with a characteristic black center. Secondary vesicles are sometimes observed, lymphadenopathy may occur, and local edema may be extensive. Patients may have fever, malaise, and headache. The most common sites of cutaneous anthrax are the hands, forearms, and head. Of the 203 cases reported in the United States since 1955 in which the site of infection was known, 64 (27%) have been in the head and neck region (2). Presumably, the mechanism of inoculation in this case was the transfer of infective spores on the patient's gloves to broken skin on his face.

Human Anthrax — Continued

Untreated, 20% of persons with cutaneous anthrax die, compared with <1% of those who receive antibiotic therapy (2,6). *B. anthracis* is sensitive *in vitro* to penicillin, tetracycline, chloramphenicol, and ciprofloxacin (7). In localized or uncomplicated cases of cutaneous anthrax, the recommended regimen is penicillin V, 500 mg taken orally every 6 hours for 5–7 days. For more severe cases of cutaneous anthrax, penicillin G, 4–6 million units every 6 hours intravenously for 7–10 days is recommended. Doxycycline, 100 mg twice a day for localized cases or intravenously for serious cases, also can be used (7–9).

Veterinarians and agricultural workers should minimize direct contact with animals suspected to have died of anthrax. For confirmation by smear or culture, the carcass should not be opened, and a postmortem blood sample should be obtained aseptically by a veterinarian from an accessible peripheral vein (e.g., jugular vein). Specimens also can be obtained from hemorrhagic nasal, buccal, or anal exudate or from materials contaminated with the exudate. If possible, the carcass should be burned or buried where it is found. To minimize environmental contamination, burning is the preferred disposal method. Bedding and other materials found around the carcass (e.g., contaminated soil) also should be burned or buried, and all remaining animals should be promptly removed from the affected pasture. Farms where anthrax deaths among livestock are confirmed should be quarantined and all susceptible healthy livestock on the affected and neighboring premises vaccinated with the Sterne vaccine. Where anthrax is suspected or confirmed, use of long-acting antibiotics followed by vaccination may be effective in reducing livestock deaths. However, this regimen has not been systematically evaluated.

Because this epizootic may continue in North Dakota and because anthrax cases among livestock occur each year, health-care providers should consider the possibility of anthrax when evaluating patients with characteristic skin lesions, particularly if the exposure history includes handling of animals with confirmed or suspected anthrax. Vigilance for human cases of anthrax should be heightened during anthrax epizootics. Veterinary health services should work closely with public and private health officials to ensure early detection and treatment of possible human anthrax cases resulting from exposure to animals during an epizootic. Any person who handles carcasses of animals that have died or are suspected to have died of anthrax should contact their health-care provider if they develop a skin lesion. Although veterinarians, agricultural workers, and laboratory workers might be at increased risk for *B. anthracis* infection during these epizootics, the risk is low and anthrax vaccination is not recommended (10).

## Botulism Outbreak Associated With Eating Fermented Food — Alaska, 2001

On January 18, 2001, the Alaska Division of Public Health was informed by a local physician of a possible botulism outbreak in a southwest Alaska village. This report summarizes the findings of the outbreak investigation, which linked disease to eating fermented food, and describes a new botulism prevention program in Alaska.

A case of foodborne botulism was defined as a clinically compatible illness in a village resident with laboratory confirmation of botulism or a history of eating the same food as a laboratory-confirmed case; 14 persons in the village had eaten fermented beaver tail and paw on January 17. Approximately 20 hours later, three of the 14 had symptoms suggestive of botulism, including dry mouth, blurry vision, and general weakness. Two patients developed respiratory failure and required intubation and mechanical ventilation. One of the two intubated patients suffered cardiac arrest and underwent successful cardiopulmonary resuscitation. Approximately 6 hours after the onset of symptoms, the three patients received types A/B and E botulism antitoxin. They subsequently were evacuated to an intensive care unit (ICU) in Anchorage. Two patients recovered without further complication. The third required tracheostomy tube placement and mechanical ventilation for 1 month; this patient had been hospitalized with botulism in 1997. Of the other 11 exposed persons, four reported minor symptoms compatible with botulism, including dry mouth and nausea, and were admitted to a hospital for overnight observation. One was hospitalized for 10 days with persistent ileus. The remaining seven exposed persons were held for observation for 48 hours.

Clinical specimens from the 14 exposed persons were tested for botulinum toxin at CDC. Type E toxin was detected in serum specimens from two of the ICU patients and in stool from the third. Although they displayed minor symptoms, the other 11 persons had no toxin found in specimens and were not considered laboratory-confirmed cases. Type E toxin also was detected in three beaver paws tested from the implicated meal.

Beaver is hunted in southwest Alaska, and certain parts often are fermented and eaten later. In this outbreak, the tail and paws had been wrapped in a paper rice sack and stored for up to 3 months in the entry of a patient's house. Some of the beaver tail and paw had been added to the sack as recently as 1 week before it was eaten.

Reported by: A Horn, K Stamper, D Dahlberg, J McCabe, MD, Bristol Bay Area Health Corporation, Dillingham; M Beller, MD, JP Middaugh, MD, State Epidemiologist, Alaska Dept of Health and Social Svcs. Arctic Investigations Program; Foodborne and Diarrheal Diseases Br, Div of Bacterial and Mycotic Diseases, National Center for Infectious Diseases; and EIS officers, CDC.

**Editorial Note:** This report illustrates how the use of nontraditional fermentation methods is associated with foodborne botulism in Alaska. Botulism results from eating preformed

#### Botulism Outbreak — Continued

toxin produced by *Clostridium botulinum*. Botulism begins with cranial nerve paralysis, including diplopia, dilated and fixed pupils, dysarthria, dysphagia, and dry throat. Botulism intoxication can result in death, which most often is caused by respiratory failure. The latent period is typically 12–36 hours but can range from 6 hours to 10 days (1). *C. botulinum* and closely related organisms produce toxins designated as types A, B, C, D, E, F, and G. Human botulism is most commonly caused by types A, B, and E. Type E is associated with foods of marine or freshwater origin. Alaska's foodborne botulism rates exceed those in any other state and are among the highest in the world (1). During 1950–2000, Alaska recorded 226 cases of foodborne botulism from 114 outbreaks. All patients were Alaska Natives, and all cases with known causes were associated with eating fermented foods (1,2). Approximately 27% of U.S. foodborne botulism cases occur in Alaska.

In traditional fermentation, food is kept in a grass-lined hole in the ground or a wooden barrel sunken into the ground or is placed in a shady area above ground for several weeks to months. Since the 1970s, however, plastic or glass containers have been used and fermentation has been done above ground or indoors. The anaerobic condition of sealed containers and warmer temperatures make fermentation more rapid and production of botulism toxin more likely (3–5). These nontraditional methods have been associated with increased botulism rates in Alaska during 1970–1989 (Figure 1) (4,5). Although a plastic container was not used in this outbreak, the beaver tail and paw were fermented in a closed rice sack and stored in a warm area.

FIGURE 1. Incidence\* of foodborne botulism among Alaska Natives, by 5-year intervals — Alaska, 1950–1999

<sup>\*</sup>Per 100,000 population.

Botulism Outbreak — Continued

Early diagnosis and antitoxin treatment have contributed to the decline of the case-fatality rate from approximately 31% during 1950–1959 to no deaths in Alaska since 1994 (1). However, Alaska continues to have high foodborne botulism rates because fermented foods are part of Alaska Native culture. In a 1999 survey, 107 (77%) of 140 Alaska Natives reported having eaten fermented foods at least once in their lifetime (3).

In 1998, the Bristol Bay Area Health Corporation, a health-care delivery organization operated by Alaska Natives in southwest Alaska, collaborated with CDC's Arctic Investigations Program to design a community-based botulism prevention strategy, including an education video entitled, "A Helping Hand: Keeping Your Family Safe From Botulism." It features Alaska Native elders and botulism survivors discussing the risks of eating improperly fermented foods and recommends returning to traditional methods. The video also suggests boiling fermented foods for 10 minutes to destroy botulinum toxin. Both an English and an Alaska Native language version of the video were produced and distributed to all village clinics and schools in the Bristol Bay region. Information on botulism prevention also is available at http://www.cdc.gov/phtn/botulism/default/default.htm.

# Self-Reported Asthma Prevalence Among Adults — United States, 2000

Asthma is a chronic inflammatory disorder of the airways characterized by episodes of wheezing, shortness of breath, chest tightness, and cough and is among the most common chronic diseases in the United States, affecting approximately 10.2 million adults during 1996 (1). Direct and indirect costs associated with asthma during 1998 were an estimated \$12.7 billion (2). Despite the prevalence and associated costs of asthma, state-specific data have not been available (3,4). This report summarizes state asthma prevalence data collected from the 2000 Behavioral Risk Factor Surveillance System (BRFSS) survey, which indicated that approximately 7.2% of adults residing in the United States reported having asthma. This is the first state-specific asthma prevalence data available for all 50 states. Continued use of the BRFSS asthma questions will allow state health departments to monitor trends in asthma prevalence and to provide data to direct asthma management.

BRFSS is a state-based, random-digit–dialed survey of the noninstitutionalized U.S. population aged ≥18 years; the survey collects information about modifiable risk factors for chronic diseases and other leading causes of death (5). CDC and state and territorial departments of health use the system to monitor trends that affect public health decisions. During 1999, the first optional two-item module on asthma was added to the BRFSS questionnaire. During 2000, the asthma questions were used in the 50 states, Puerto Rico, and the District of Columbia. Two asthma case definitions were constructed. Lifetime asthma was defined as answering "yes" to "Have you ever been told by a doctor that you have asthma?" Current asthma was defined as answering "yes" to "Have you ever been told by a doctor that you have asthma?" and "Do you still have asthma?" Weighted prevalence estimates and 95% confidence intervals were calculated using SUDAAN to account for the complex survey design (6).

The median response rate was 51.3% (from 33.4% in New Jersey to 75.5% in Minnesota). On the basis of answers from 182,293 respondents, the overall prevalence of lifetime asthma was 10.5%. The median rate of lifetime asthma from the 52 reporting areas was also 10.5% (from 8.0% in Louisiana to 15.9% in Puerto Rico) (Table 1). During 2000, an estimated 14.6 million adults had current asthma; the overall prevalence of current asthma was 7.2%. The median rate of current asthma from the 52 reporting areas was 7.3% (from 5.0% in Louisiana to 8.9% in Maine) (Table 1). Current asthma was higher among blacks (8.5%) than whites (7.1%) and persons of other race/ethnicity (5.6%). The prevalence of current asthma decreased with increasing family income (from 9.8% among persons with family incomes of <\$15,000 to 5.9% among persons with family incomes of ≥\$75,000). Women had higher rates of current asthma than men both overall (9.1% versus 5.1%) and in each reporting area (Table 2).

Reported by the following BRFSS coordinators: S Reese, Alabama; P Owen, Alaska; R Weyant, Arizona; B Woodson, Arkansas; B Davis, California; M Leff, Colorado; M Adams, Connecticut; F Breukelman, Delaware; I Bullo, District of Columbia; S Oba, Florida; L Martin, Georgia; F Reyes-Salvail, Hawaii; J Aydelotte, Idaho; B Steiner, Illinois; L Stemnock, Indiana; J Davila, Iowa; C Hunt, Kansas; T Sparks, Kentucky; B Bates, Louisiana; D Maines, Maine; A Weinstein, Maryland; D Brook, Massachusetts; H McGee, Michigan; N Salem, Minnesota; D Johnson, Mississippi; J Jackson, Missouri; P Feigley, Montana; L Andelt, Nebraska; E DeJan, Nevada; J Taylor, New Hampshire; G Boeselager, New Jersey; W Honey, New Mexico; C Baker, New York; Z Gizlice, North Carolina; L Shireley, North Dakota; P Coss, Ohio; K Baker, Oklahoma; K Pickle, Oregon; L Mann, Pennsylvania; Y Cintron, Puerto Rico; J Hesser, Rhode Island; M Wu, South Carolina; M Gildemaster, South Dakota; D Ridings, Tennessee; K Condon, Texas; K Marti, Utah; C Roe, Vermont; J Hicks, Virginia; K Wynkoop-Simmons, Washington; F King, West Virginia; K Pearson, Wisconsin; M Futa, Wyoming. Air Pollution and Respiratory Health Br, Div of Environmental Hazards and Health Effects, National Center for Environmental Health; and an EIS Officer, CDC.

**Editorial Note**: This report provides the first estimates of self-reported asthma in U.S. adults collected and reported at the state level. Previous state estimates were calculated using National Health Interview Survey regional data and demographic data from the states. In 1998, national prevalence of current asthma among adults and children was 6.4% (from 5.8% in Florida, Oklahoma, and West Virginia to 7.2% in Nevada) (7). BRFSS data indicate no consistent regional pattern and some variability among the states. Possible reasons for this variability include demographic, socioeconomic (e.g., income and education levels) and environmental factors (e.g., outdoor air pollution and climate), physician diagnostic procedures, or response rates. Asthma rates consistently were

<sup>\*</sup> Answering "yes" to "Have you ever been told by a doctor that you have asthma?"

† Answering "yes" to "Have you ever been told by a doctor that you have asthma?" and "Do you still have asthma?"

§ Confidence interval.

<sup>&</sup>lt;sup>¶</sup> Estimates are inexact because Illinois deviated from standard BRFSS sampling methodology.

TABLE 2. Estimated current asthma\* prevalence, by sex — Behavioral Risk Factor Surveillance System (BRFSS), United States, Puerto Rico, and the District of Columbia, 2000

<sup>\*</sup> Answering "yes" to "Have you ever been told by a doctor that you have asthma?" and "Do you still have asthma?"

<sup>†</sup> Confidence interval.

<sup>§</sup> Estimates are inexact because Illinois deviated from standard BRFSS sampling methodology.

higher among women than men. Higher rates among women have been described for both prevalence and other measures of asthma (e.g., hospitalization and mortality) (3) and may be associated with hormones, obesity, or other factors (8,9). It is unclear whether variability in rates reflects a true difference in prevalence, differences in reporting, or other factors.

The findings in this report are subject to at least three limitations. First, the median response rate for the survey was only 51.3%. Second, BRFSS does not measure asthma prevalence in institutionalized adults, persons aged <18 years, and residents without telephones; the percentage of households with telephones ranges from 87% (Mississippi) to 98% (Massachusetts) (6). Third, the validity of self-reported asthma status in BRFSS is unknown. BRFSS case definitions include respondents who have been told by a physician that they have asthma; either the physician's diagnosis or the subjects' recall of that diagnosis may be inaccurate. A 1998 review of asthma questionnaires reported a mean sensitivity of 68% (range: 48%–100%) and a mean specificity of 94% (range: 78%–100%) when self-reported asthma was compared with a clinical diagnosis of asthma (10).

The continued use of the BRFSS asthma questions will allow state health departments to monitor trends in asthma prevalence and to provide data to direct asthma management. In addition, the data will provide state-specific information on asthma prevalence by age, race/ethnicity, education level, and family income.

## Draft of Guidelines for the Prevention of Opportunistic Infections (OIs) in Persons Infected with Human Immunodeficiency Virus

The 2001 Guidelines for the Prevention of Opportunistic Infections (Ols) in Persons Infected with Human Immunodeficiency Virus are now available in draft form on the AIDS Treatment and Information Service website (http://www.hivatis.org). These guidelines, originally published in 1995 and revised in 1997 and 1999, address prevention of 19 HIV-associated Ols, or groups of Ols, with regard to preventing exposure to the infectious agent, preventing disease by chemoprophylaxis or vaccination (primary prophylaxis), and preventing disease recurrence in persons already treated for an OI (secondary prophylaxis). The guidelines include recommendations for adults and children, with specific information on care of pregnant women. As in earlier editions of the guidelines, recommendations are rated using a system that indicates the strength of each recommendation and quality of evidence supporting it.

The primary changes in the 2001 guidelines pertain to discontinuing chemoprophylaxis in patients whose CD4+ lymphocyte counts have increased in response to highly active antiretroviral therapy. Since the 1999 guidelines, new or strengthened recommendations are offered concerning discontinuation of primary prophylaxis against *Pneumocystis carinii* pneumonia (PCP), toxoplasmic encephalitis (TE), and disseminated *Mycobacterium avium* complex (MAC) disease; and for discontinuation of secondary prophylaxis against PCP, cytomegalovirus retinitis, disseminated MAC, TE, and cryptococcal meningitis. Other changes include new information on drug interactions and revised recommendations for vaccinating HIV-exposed/infected children.

The 2001 guidelines were developed by representatives of U.S. government agencies, professional organizations, academic institutions, and patient advocacy groups after reviewing published manuscripts, abstracts, and material presented at scientific meetings.

Comments on the guidelines may be addressed to Henry Masur, M.D., <a href="https://www.nih.gov">https://www.nih.gov</a> and will be accepted until September 1, 2001. After this date, the document will be revised and finalized. The guidelines are expected to be updated periodically as new information becomes available.

## **Epidemiology in Action**

CDC and Emory University's Rollins School of Public Health will co-sponsor a course, "Epidemiology in Action" from November 5–16, 2001, at CDC and Emory University campuses. The course is designed for state and local public health professionals.

The course emphasizes the practical application of epidemiology to public health problems and will consist of lectures, workshops, classroom exercises (including actual epidemiologic problems), and roundtable discussions. Topics include descriptive epidemiology and biostatistics, analytic epidemiology, epidemic investigations, public health

U: Unavailable. -:No reported cases.

\*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

¹Pneumonia and influenza.

<sup>\*</sup>Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

\*Total includes unknown ages.

Michele D. Renshaw Erica R. Shaver The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr-toc. Electronic copy also is available from CDC's World-Wide Web server at http://www.cdc.gov/mmwr or from CDC's file transfer protocol server at ftp://ftp.cdc.gov/pub/Publications/mmwr. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly MMWR are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the MMWR Series, including material to be considered for publication, to: Editor, MMWR Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.
