Morbidity and Mortality Weekly Report

March 2, 2012

## HIV Infection and HIV-Associated Behaviors Among Injecting Drug Users — 20 Cities, United States, 2009

Despite a recent reduction in the number of human immunodeficiency virus (HIV) infections attributed to injecting drug use in the United States (1), 9% of new U.S. HIV infections in 2009 occurred among injecting drug users (IDUs) (2). To monitor HIV-associated behaviors and HIV prevalence among IDUs, CDC's National HIV Behavioral Surveillance System (NHBS) conducts interviews and HIV testing in selected metropolitan statistical areas (MSAs). This report summarizes data from 10,073 IDUs interviewed and tested in 20 MSAs in 2009. Of IDUs tested, 9% had a positive HIV test result, and 45% of those testing positive were unaware of their infection. Among the 9,565 IDUs with HIV negative or unknown HIV status before the survey, 69% reported having unprotected vaginal sex, 34% reported sharing syringes, and 23% reported having unprotected heterosexual anal sex during the 12 previous months. Although these risk behavior prevalences appear to warrant increased access to HIV testing and prevention services, for the previous 12-month period, only 49% of the IDUs at risk for acquiring HIV infection reported having been tested for HIV, and 19% reported participating in a behavioral intervention. Increased HIV prevention and testing efforts are needed to further reduce HIV infections among IDUs.

NHBS monitors HIV-associated behaviors and HIV prevalence among populations at high risk for acquiring HIV. In 2009, NHBS staff members in 20 MSAs with high prevalence of acquired immunodeficiency syndrome (AIDS)\* collected cross-sectional behavioral risk data and conducted HIV testing among IDUs using respondent-driven sampling, a peer-referral sampling method (3,4). Recruitment chains in each city began with one to 15 initial participants recruited by NHBS staff members during formative assessment and planning. Initial participants who completed the interview were asked to recruit up to five other IDUs through use of a coded coupon system designed to track referrals. Recruitment continued for multiple waves; all participation was voluntary. Persons were eligible to participate if they had injected drugs during the previous 12 months, resided in the MSA, and could complete the interview in English or Spanish. After participants gave oral informed consent, in-person interviews were conducted by trained interviewers who administered a standardized, anonymous questionnaire about HIV-associated behaviors. All respondents were offered anonymous HIV testing, which was performed by collecting blood or oral specimens for either rapid testing in the field or laboratory-based testing. A nonreactive rapid test result was considered HIV negative; a reactive rapid test result was considered HIV positive if confirmed by Western blot or indirect immunofluorescence assay. Incentives were offered for participating in the interview, completing an HIV test, and for recruiting IDUs to participate.<sup>†</sup>

For this report, data on HIV testing and 13 HIV-associated behaviors were analyzed. Participants were asked whether, in the previous 12 months, they 1) had shared syringes; 2) had shared injection equipment other than syringes; 3) had vaginal

### **INSIDE**

- 139 Exposure to Nitrogen Dioxide in an Indoor Ice Arena — New Hampshire, 2011
- 143 Chronic Obstructive Pulmonary Disease and Associated Health-Care Resource Use — North Carolina, 2007 and 2009
- 147 Announcement

<sup>\*</sup>The 20 MSAs were Atlanta, Georgia; Baltimore, Maryland; Boston, Massachusetts; Chicago, Illinois; Dallas, Texas; Denver, Colorado; Detroit, Michigan; Houston, Texas; Los Angeles, California; Miami, Florida; Nassau-Suffolk, New York; New Orleans, Louisiana; New York, New York; Newark, New Jersey; Philadelphia, Pennsylvania; San Diego, California; San Francisco, California; San Juan, Puerto Rico; Seattle, Washington; and Washington, District of Columbia.

<sup>&</sup>lt;sup>†</sup>The incentive format (cash or gift card) and amount varied by MSA based on formative assessment and local policy. A typical format included \$25 for completing the interview, \$25 for providing a specimen for HIV testing, and \$10 for each successful recruitment (maximum of five).

sex; 4) had unprotected vaginal sex; 5) had heterosexual anal sex; 6) had unprotected heterosexual anal sex; 7) had male-male anal sex; 8) had unprotected male-male anal sex; 9) had more than one opposite sex partner; 10) had been tested previously for HIV infection; and 11) had participated in an HIV behavioral intervention. In addition, participants were asked whether they had ever been tested for 12) HIV or 13) hepatitis C virus (HCV) infection. IDUs who tested HIV positive during the survey were defined as unaware of their HIV infection if they had reported that their most recent previous HIV test result was negative, indeterminate, or unknown, or that they had never been tested. IDUs with self-reported negative, indeterminate, or unknown status (including those who tested positive during the survey), were considered to be at risk for acquiring HIV. Data from each MSA were analyzed using a respondent-driven sampling analysis tool that produces estimates adjusted for differences in peer recruitment patterns and size of participant IDU peer networks. Results from these analyses were aggregated and weighted by the size of the IDU population in each MSA (5) to obtain estimates overall.

In 2009, a total of 13,186 persons were recruited to participate; of these, 2,687 (20%) were found ineligible. An additional 426 (3%) eligible participants were excluded from analysis.\*\* Data for the remaining 10,073 participants were used in the analysis of HIV prevalence and participant awareness of serostatus (Table 1). To focus the analysis of HIV-associated behaviors on persons at risk for acquiring HIV infection, 508 participants who reported that they previously had tested positive for HIV were excluded (Table 2).

Among 10,073 IDUs, 9% tested positive for HIV. Prevalence of HIV infection was higher among Hispanics (12%) and non-Hispanic blacks (11%) than non-Hispanic whites (6%). IDUs in the Northeast and South regions had higher HIV prevalence (12% and 11%) than those in the Midwest and West regions

<sup>§</sup> Sharing syringes was defined as "using needles that someone else had already injected with." Sharing injection equipment was defined as using cookers, cottons, or water to rinse needles or prepare drugs "that someone else had already used." Unprotected vaginal and anal sex were defined as "sex without a condom." Male-male anal sex was restricted to males and includes both insertive and receptive anal sex. Participating in an individual or group HIV behavioral intervention (e.g., a one-on-one conversation with a counselor or an organized discussion regarding HIV prevention) did not include counseling received as part of an HIV test. Testing for HCV infection was measured as ever tested or ever received a diagnosis of hepatitis C.

<sup>9</sup> City-level estimates with inadequate sample size for analysis (five or fewer observations) were excluded from aggregation. For city-level estimates for which confidence intervals could not be calculated, maximally wide confidence intervals (0–1) were used in aggregation. Such estimates represented <4% of the analysis.</p>

<sup>\*\*</sup> Data from 426 participants were excluded because of missing recruitment data (five participants), lost data during electronic upload (142), incomplete survey data (25), survey responses with questionable validity (63), invalid HIV test results (130), could not be identified as male or female (53), or other reason (eight). Reasons for exclusion were not mutually exclusive and were applied hierarchically in the order listed.

- \* The National HIV Behavioral Surveillance System covers the following 20 metropolitan statistical areas (MSAs): Atlanta, Georgia; Baltimore, Maryland; Boston, Massachusetts; Chicago, Illinois; Dallas, Texas; Denver, Colorado; Detroit, Michigan; Houston, Texas; Los Angeles, California; Miami, Florida; Nassau-Suffolk, New York; New Orleans, Louisiana; New York, New York; Newark, New Jersey; Philadelphia, Pennsylvania; San Diego, California; San Francisco, California; San Juan, Puerto Rico; Seattle, Washington; and Washington, District of Columbia.
- <sup>†</sup> Percentages were weighted to adjust for differences in recruitment, the size of participants' networks of IDUs, and the size of the population of IDUs in each MSA.
- § Includes American Indian/Alaska Natives, Asians, Native Hawaiian or other Pacific Islanders, and persons of multiple races.
- Other drugs injected alone or two or more drugs injected with the same frequency.
- \*\*\* The Northeast region includes the MSAs of Boston, Massachusetts; Nassau-Suffolk, New York; New York, New York; Newark, New Jersey; and Philadelphia, Pennsylvania. South region includes Atlanta, Georgia; Baltimore, Maryland; Dallas, Texas; Houston, Texas; Miami, Florida; New Orleans, Louisiana; and Washington, District of Columbia. Midwest region includes Chicago, Illinois and Detroit, Michigan. West region includes Denver, Colorado; Los Angeles, California; San Diego, California; San Francisco, California; and Seattle, Washington. San Juan, Puerto Rico, was not included.

(5% and 6%). Those with less than a high school education had higher HIV prevalence (13%) than IDUs who completed high school (8%) or had more than high school education (7%)

#### What is already known on this topic?

Injecting drug users (IDUs) in the United States are at increased risk for acquiring human immunodeficiency virus (HIV) infection. Surveys of IDUs entering drug treatment centers during 1993–1997 found local HIV prevalence ranging from 1% to 37% and an overall prevalence of 18%.

#### What is added by this report?

The National HIV Behavioral Surveillance System recruited 10,073 IDUs from 20 U.S. metropolitan statistical areas to be interviewed and tested for HIV infection in 2009. Nine percent tested positive for HIV, of whom 45% were unaware of their infection. Among those at risk for acquiring HIV infection, 34% reported sharing syringes, and 69% reported having unprotected vaginal sex in the previous 12 months.

#### What are the implications for public health practice?

Many IDUs are at risk for acquiring HIV infection because of their drug use practices and sexual behaviors, and a substantial percentage of IDUs in urban areas with high HIV prevalence are already infected but unaware of their infection. To prevent infections, IDUs need ready access to HIV testing, new sterile syringes, condoms, and substance abuse treatment.

(Table 1). Among HIV-infected IDUs, 45% (95% confidence interval [CI] = 38%–51%) were unaware of their infection.

Among the 9,565 IDUs at risk for acquiring HIV infection and responding to questions regarding HIV-associated behaviors in the previous 12 months, 34% reported sharing syringes, 46% reported multiple opposite sex partners, 69% reported unprotected vaginal sex, and 23% reported unprotected heterosexual anal sex. In addition, 19% reported participating in an HIV behavioral intervention, and 49% reported having had an HIV test (Table 2).

Among the IDUs at risk for acquiring HIV infection, 72% reported ever being tested for HCV infection (Table 2), and 89% (CI = 88%–90%) reported ever having an HIV test. Among male IDUs at risk for acquiring HIV infection, 7% (CI = 5%–8%) reported male-male anal sex in the previous 12 months, and 5% (CI = 3%–7%) reported unprotected male-male anal sex in the previous 12 months.

The prevalence of HIV-associated risk behaviors in the previous 12 months generally decreased with increasing age. For example, among persons aged 18–29 years, 52% reported sharing syringes, compared with 39% aged 30–39 years, 34% aged 40–49 years, and 25% aged ≥50 years. A higher percentage of IDUs with less than a high school education reported sharing syringes (38%), compared with high school graduates (32%) or those with higher education (31%). Lower percentages of IDUs with less than a high school education reported participation in HIV interventions (16%) and testing for HCV infection (67%), compared with those with a high school education (20% and 73%, respectively) and those with higher

DiNenno, PhD, Amanda Smith, MPH, Nevin Krishna, MS, Amy Lansky, PhD, Div of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, CDC. Corresponding contributor: Cyprian Wejnert, cwejnert@cdc.gov, 404-639-6044.

#### **Editorial Note**

The 2009 data in this report provide the first estimates from a large-scale survey of HIV seroprevalence among IDUs since 1993–1997, when CDC conducted anonymous HIV testing among IDUs entering drug treatment centers in 14 MSAs (6). In the study of IDUs entering drug treatment, HIV prevalence was found to be 18% (range by MSA = 1%–37%). In this analysis, 9% of IDUs tested positive for HIV infection. Furthermore, 45% of those testing positive were unaware of their infection.

Risk behavior prevalences in this report showing that IDUs are at risk for acquiring HIV infection through their sexual behavior in addition to their drug use practices are similar to previously reported NHBS surveillance data (7). Compared with a similar analysis of IDUs interviewed during 2005–2006,

TABLE 2. §§ Other drugs injected alone or two or more drugs injected with the same frequency.

lower percentages in this 2009 study reported receiving HIV interventions (19% compared with 30%) and HIV testing (49% compared with 66%) in the previous 12 months (7). These results highlight the need for expanded HIV testing and prevention among IDUs. The combination of declining HIV prevalence and high-risk behavior represent a critical intervention opportunity to further reduce HIV prevalence and incidence among IDUs.

Consistent with previous reports (8), this analysis found higher HIV prevalence among Hispanic and non-Hispanic black IDUs than non-Hispanic white IDUs. However, minority IDUs were neither more nor less likely to have received HIV testing, participated in HIV behavioral interventions, or engaged in risk behaviors than white IDUs in the 12 months preceding the NHBS interview. These data suggest factors not assessed by this study might be contributing to racial/ethnic disparities in HIV prevalence among IDUs.

The findings in this report are subject to at least three limitations. First, some participants might not have accurately reported their behavior to interviewers, and results might be affected by social desirability bias. Second, because no method of obtaining

probability samples of IDUs exists, the representativeness of the NHBS sample cannot be determined. Although respondent-driven sampling adjusts for some selection biases (4), other biases might have affected the sample. Finally, IDUs were interviewed in 20 MSAs with high AIDS prevalence; findings from these cities might not be generalizable to other cities or states.

To reduce the number of new HIV infections, the National HIV/AIDS Strategy<sup>††</sup> calls for intensifying prevention efforts in communities where HIV is most heavily concentrated. CDC's high impact prevention approach<sup>§§</sup> is an essential step toward achieving the goals of the national strategy. HIV prevention strategies for IDUs, including HIV testing and linkage to care, prevention and care for HIV-infected IDUs, and access to new sterile syringes, ¶ have been shown to be effective. Targeted, effective approaches to HIV prevention will help reduce the number of new HIV infections among IDUs.

<sup>\*</sup> Percentages were weighted to adjust for differences in recruitment, the size of participants' networks of IDUs, and the size of the population of IDUs in each metropolitan statistical area (MSA).
† IDUs at risk for acquiring HIV infection were defined as those reporting having never had an HIV test or that their most recent HIV test result was negative, indeterminate, or unknown.

Sharing syringes was defined as "using needles that someone else had already injected with," and sharing injection equipment was defined as using equipment such as cookers, cottons, or water used to rinse needles or prepare drugs "that someone else had already used." Unprotected vaginal sex/Unprotected anal sex was defined as "sex without a condom." Participating in an individual or group HIV behavioral intervention (e.g., a one-on-one conversation with a counselor or an organized discussion regarding HIV prevention) did not include counseling received as part of an HIV test.

The National HIV Behavioral Surveillance System covers the following MSAs: Atlanta, Georgia; Baltimore, Maryland; Boston, Massachusetts; Chicago, Illinois; Dallas, Texas; Denver, Colorado; Detroit, Michigan; Houston, Texas; Los Angeles, California; Miami, Florida; Nassau-Suffolk, New York; New Orleans, Louisiana; New York; New York; New Jersey; Philadelphia, Pennsylvania; San Diego, California; San Francisco, California; San Juan, Puerto Rico; Seattle, Washington; and Washington, District of Columbia.

<sup>\*\*</sup> Testing for hepatitis C virus infection was measured as ever tested or ever received a diagnosis of hepatitis C. All other behaviors are reported for the previous 12 months.

<sup>19</sup> The Northeast region includes the MSAs of Boston, Massachusetts; Nassau-Suffolk, New York; New York; New York; New Jersey; and Philadelphia, Pennsylvania. South region includes Atlanta, Georgia; Baltimore, Maryland; Dallas, Texas; Houston, Texas; Miami, Florida; New Orleans, Louisiana; and Washington, District of Columbia. Midwest region includes Chicago, Illinois and Detroit, Michigan. West region includes Denver, Colorado; Los Angeles, California; San Diego, California; San Francisco, California; and Seattle, Washington. San Juan, Puerto Rico, was not included.

## Exposure to Nitrogen Dioxide in an Indoor Ice Arena — New Hampshire, 2011

In January 2011, the New Hampshire Department of Health and Human Services (NHDHHS) investigated acute respiratory symptoms in a group of ice hockey players. The symptoms, which included cough, shortness of breath, hemoptysis, and chest pain or tightness, were consistent with exposure to nitrogen dioxide gas (NO<sub>2</sub>), a byproduct of combustion. Environmental and epidemiologic investigations were begun to determine the source of the exposure and identify potentially exposed persons. This report summarizes the results of those investigations, which implicated a local indoor ice arena that had hosted two hockey practice sessions during a 24-hour period when the arena ventilation system was not functioning. A total of 43 exposed persons were interviewed, of whom 31 (72.1%) reported symptoms consistent with NO<sub>2</sub> exposure. The highest attack rate was among the hockey players (87.9%). After repair of the ventilation system, no additional cases were identified. To prevent similar episodes, ice arena operators should ensure ventilation systems and alarms are operating properly and that levels of NO<sub>2</sub> and carbon monoxide (CO) are monitored continuously for early detection of increased gas levels.

On January 4, 2011, NHDHHS was notified that a previously healthy male aged 19 years was hospitalized for sudden onset of cough, shortness of breath, and hemoptysis shortly after a team ice hockey practice. His physical examination was notable for crackles heard in both lung bases, and his oxygen saturation was decreased to 88%–91% on room air (normal: >95%). Bilateral infiltrates and nodules were observed on chest computed tomography. Investigation revealed that other members of his team (team A) and at least one player from another local team (team B) were experiencing similar symptoms and independently had been directed to local emergency departments. Both teams had practiced in the same ice arena on the evening of January 3.

Further investigation revealed that on the morning of January 3, the ventilation system circuit board failed while being serviced, making the ventilation system inoperable. Two arena workers then spent 60–90 minutes resurfacing the ice using propane-powered equipment, finishing at approximately 11:30 a.m. The workers later reported observing a yellow haze over the ice, but neither reported any symptoms. Team A's practice was held from 6:00 to 8:00 p.m., and team B's practice was from 8:00 to 10:00 pm. The yellow haze was noted by players, coaches, and spectators at both practices. The next morning, January 4, at 9 a.m., the circuit board was replaced, and the ventilation system began operating normally. No other

exposures had occurred during the time the ventilation system was not functional.

The arena housed a standard-sized ice hockey rink and was owned by a private school. The rink ice was maintained using propane-powered ice-resurfacing machines. The arena had an air monitoring system for CO and carbon dioxide  $(CO_2)$ , but not for  $NO_2$ .

On the evening of January 4, NHDHHS staff members began interviewing all 33 players and five coaches who were present at practices on January 3. From these initial interviews, case finding was expanded to include four practice spectators and the two arena workers who operated the resurfacing equipment, for a total of 44 exposed persons. Questionnaires that assessed symptoms, exposures, and environmental observations were administered by NHDHHS staff members in person or by telephone. All but one of the 44 exposed persons completed the questionnaire.

A case was defined as the onset of cough, hemoptysis, chest pain, chest tightening, shortness of breath, headache, dizziness, nausea, or vomiting within 48 hours of being in the ice arena from 11:00 a.m. on Monday, January 3, to 9:00 a.m. on Tuesday, January 4. Illnesses with symptoms consistent with the common cold (e.g., runny nose, fever, and head congestion) were not counted as cases. Using this definition, 31 cases were identified among the 43 persons interviewed: 29 among the 33 players (87.9%) and two among the five coaches (40%). None of the four spectators had illness consistent with the case definition, nor did the one arena worker who completed the questionnaire. Most patients (90.3%) had two or more symptoms (Table 1). Although 10 nonplayers (coaches, spectators, and arena personnel) were exposed, players were nearly four times as likely to become ill (87.9% versus 20.0%, risk ratio [RR] = 4.39, 95% confidence interval [CI] = 1.26–15.28). Compared with nonplayers, players also were more likely to have spent more time on the ice (defined as >1 hour versus  $\leq 1$  hour) (84.8% versus 40.0%, RR = 2.12, CI = 0.98–4.59). As time spent on the ice increased, so did the attack rate and amount of hemoptysis (Figure).

On January 5, the New Hampshire Department of Environmental Services (NHDES) and the New Hampshire State Fire Marshal's Office (NHFMO) inspected the ice arena. Measurements for CO and NO<sub>2</sub> were taken before running the resurfacing equipment (baseline conditions) and while operating the equipment, and recorded at breathing zone (where persons on the ice would be exposed) as well as adjacent to the equipment exhaust pipe. Air sampling was performed for NO<sub>2</sub> using a Gastec piston hand pump equipped with Sensidyne

TABLE 1. Number and percentage of persons with symptoms consistent with exposure to nitrogen dioxide gas  $(NO_2)$  in an indoor ice arena (N=31) — New Hampshire, January 3, 2011

Symptom	No.	(%)
Cough	26	(83.9)
Shortness of breath	24	(77.4)
Chest tightness	20	(64.5)
Chest pain	14	(45.2)
Weakness	11	(35.5)
Sore throat	11	(35.5)
Nausea/Vomiting	10	(32.3)
Hemoptysis/Bloody sputum*	8	(25.8)
Throat irritation	8	(25.8)
Headache	8	(25.8)
Abdominal pain	6	(19.4)
Eye irritation	5	(16.1)
Dizziness	1	(3.2)
Choking	1	(3.2)

<sup>\*</sup> Includes two persons with late-onset hemoptysis reported at follow-up survey.

colorimetric gas detector tubes. A TSI Q-Trak indoor air quality monitor was used to obtain direct readings for CO. While the ice resurfacer was operating in the arena, the NO<sub>2</sub> concentration in the breathing zone increased, reaching 0.5 parts per million, the level at which corrective action must be taken according to regulations in states that regulate indoor air quality in ice arenas (Table 2). These measurements did not simulate actual conditions in the arena on January 3 because the arena ventilation system had been fully functional for approximately 24 hours at the time of sampling.

Beginning January 20, a follow-up questionnaire was administered to exposed persons to assess late-onset and persistent symptoms. Thirty-nine (90.7%) of the original 43 persons interviewed responded to the follow-up questionnaire. No new cases were identified; however, two of the original patients reported late onset of hemoptysis (at 5 days and 21 days postexposure) and were advised to seek medical evaluation. Six patients (20%) reported persistent symptoms: shortness of breath on exertion (four cases), cough (two cases), and fatigue (one case).

NHDHHS, in consultation with the Northern New England Poison Center, recommended that all exposed persons seek medical evaluation, even if asymptomatic, preferably at a designated occupational health clinic. Ultimately, 39 (90.6%) complied (30 of 31 [96.8%] patients and nine of 12 [75.0%] of persons without symptoms). After these initial medical evaluations, the need for follow-up was determined on a case-by-case basis, dependent on severity. NHDES and NHFMO recommended that the arena include an NO<sub>2</sub> sensor in the air monitoring system, establish alarm set points for CO and NO<sub>2</sub> in line with air action level recommendations (Table 2), and test this system at least monthly. The arena also was advised to conduct maintenance and tailpipe emissions testing on all ice resurfacing equipment at the beginning of the ice arena season

#### What is already known on this topic?

Combustion byproducts are a known threat to indoor air quality in ice arenas; however, nitrogen dioxide gas (NO<sub>2</sub>) is monitored less frequently than carbon monoxide, and signs and symptoms of NO<sub>2</sub> intoxication are less well known than those of carbon monoxide.

#### What is added by this report?

The use of propane-powered ice-resurfacing equipment for 60-90 minutes in an indoor ice arena without an operating ventilation system caused symptoms of  $NO_2$  intoxication in 31 of 43 exposed persons, including 31 of 42 persons who first entered the arena more than 6 hours after the ice resurfacing had been completed.

#### What are the implications for public health practice?

Because exposure to  $NO_2$  can occur more frequently than is recognized, public health agencies should consider educating ice arena operators about the importance of arena ventilation, air monitoring for combustion gases, and maintenance of propane-powered equipment, if use of electric ice resurfacing equipment is not feasible. Additionally, ice arena operators as well as ice hockey players and coaches who use indoor rinks should be familiar with the signs and symptoms of  $NO_2$  toxicity.

and at least once during the season, and consider installing catalytic converters to reduce emissions. However, the most reliable way to prevent exposure in this setting is to replace propane-powered equipment with electric equipment, which should be considered as a long-term solution.

#### **Editorial Note**

Respiratory illness caused by  $NO_2$  in indoor hockey rinks has been documented infrequently in the literature. Hazardous levels of  $NO_2$  in ice arenas often result from malfunction of propane-fueled ice resurfacing equipment or arena ventilation systems (1–5).

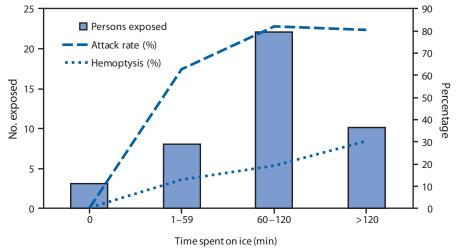

TABLE 2. Air quality recommendations for ice arena owners and managers

Recommendation	Description
Air quality in ice arenas: action steps*	Educate workers on their role in indoor air quality and protecting occupants.
	Establish a system of monitoring air quality
	Establish procedures for responding to indoor air complaints and emergencies
	Provide continuous ventilation whenever a rink is occupied
	• At a minimum, use ventilation requirements for sports arenas as described in the ASHRAE <i>Ventilation for Acceptable Indoor Air Quality, Standard 62.1-2007</i> (or most recent edition)
	$\bullet \ \ Ensure\ that\ fresh\ air\ intake\ is\ not\ blocked\ and\ not\ located\ near\ the\ exhaust\ from\ loading\ docks\ and\ outside\ idling\ vehicles$
	• Consider replacing older equipment that does not meet current Environmental Protection Agency emissions standards with newer compliant equipment or upgrade to most efficient burning fuel type and pollution control devices
	• Warm up resurfacing equipment in a well-ventilated room or a room equipped with a local exhaust
	• Use ice edgers only when the ventilation system can adequately exhaust the emissions. Keep arena gates open when resurfacing to allow for adequate ventilation of the ice area
	Keep resurfacing equipment well maintained daily and serviced annually by a qualified technician
Air action levels <sup>†</sup>	• Immediate evacuation level: 85 ppm for CO or 2 ppm for NO <sub>2</sub>

 $Abbreviations: A SHRAE = American Society of Heating, Refrigeration and Air-conditioning Engineers; CO = carbon monoxide; NO_2 = nitrogen oxide. \\$ 

Corrective action level: 25 ppm for CO or 0.5 ppm for NO<sub>2</sub>

FIGURE. Outcomes among persons exposed to nitrogen dioxide gas (NO<sub>2</sub>) in an indoor ice arena (N = 43), by time spent on ice — New Hampshire, January 3, 2011\*

<sup>\*</sup> Cochran-Armitage test for trend: attack rate, p=0.01; hemoptysis, p=0.06.

Most ice arenas are designed to minimize natural ventilation in an effort to keep warm air away from the ice surface and the ice temperature near freezing. This can create a thermal inversion in which cold air and gases (especially NO2, which is denser than air) become trapped over the ice (6). The protective glass between spectator stands and the ice rink creates an additional barrier to airflow. In this episode, exposure was made worse by prolonged use of propane-powered ice resurfacers while the ventilation system was off.

Nitrogen dioxide is a yellow to reddish brown gas that irritates the upper and lower respiratory tracts and can cause short-term central nervous system symptoms (6). Severity of symptoms is related to duration of NO<sub>2</sub> exposure (5,6), although exertion with increased frequency and depth of respiration might have made the hockey players more susceptible than the spectators or coaches to the effects of the gas. This has been reported during other exposures (4). No specific antidote for NO<sub>2</sub> toxicity exists, and therapy is focused on supportive care and prolonged monitoring (6). The longterm consequences of acute NO2 exposure are not well understood, but in this instance, six of 31 persons had persistent symptoms up to 4 weeks postexposure. Other studies document self-reported symptoms several

weeks after exposure (4), 6 months postexposure (1), and even 5 years postexposure (7). However, tests of pulmonary function (e.g., spirometry and bronchoprovocation) at 10 days, 2 months, and 6 months postexposure have provided little objective evidence of compromised lung function (1,4). The small but unpredictable potential for delayed development of life-threatening conditions such as bronchiolitis obliterans

warrants follow-up of exposed persons (6).

<sup>\*</sup> Source: US Environmental Protection Agency. Indoor air quality and ice arenas. Washington, DC: US Environmental Protection Agency; 2010. Available at http:// www.epa.gov/iag/icearenas.html.

<sup>†</sup> No federal recommendations or regulations exist for air action levels in ice arenas. These recommendations are taken from Minnesota Department of Health Interim Regulations 4620 and Massachusetts Department of Public Health Regulation 105 CMR 675.000.

The findings in this report are subject to at least two limitations. First, a broad case definition was used to ensure complete case finding and appropriate follow-up; however, this might have led to inflation of the attack rate. Second, with the exception of the index case, symptom data were based on self-report, which also might have inflated the attack rate.

No federal regulations exist for indoor air quality in ice arenas, and only three states have enacted regulations (Minnesota, Rhode Island, and Massachusetts). Only Minnesota and Massachusetts specify limits for NO<sub>2</sub> levels. After this incident, NHFMO sent an informational bulletin to all indoor ice arenas in the state based, in part, on recommendations from the U.S. Environmental Protection Agency and the regulations existing in other states (Table 2). Without legislated regulations, however, direct education of the public about signs and symptoms of NO<sub>2</sub> exposure and education of arena staff about the risk of NO<sub>2</sub> toxicity is important for prevention.

# Chronic Obstructive Pulmonary Disease and Associated Health-Care Resource Use — North Carolina, 2007 and 2009

Chronic obstructive pulmonary disease (COPD), including emphysema and chronic bronchitis, is a progressive condition in which airflow becomes limited, making it difficult to breathe. Chronic lower respiratory diseases, primarily COPD, are the third leading cause of death in the United States (1), and 5.1% of U.S. adults report a diagnosis of emphysema or chronic bronchitis (2). Smoking is the primary cause of COPD, and at least 75% of COPD deaths are attributable to smoking in the United States (3). Information on statespecific prevalence of COPD is sparse (4), as are data on the use of COPD-related health-care resources. To understand how COPD affects adults in North Carolina and what resources are used by persons with COPD, 2007 and 2009 data from the North Carolina COPD module of the Behavioral Risk Factor Surveillance System (BRFSS) were analyzed. Among 26,227 respondents, 5.7% reported ever having been told by a health professional that they had COPD. Most adults with COPD reported ever having had a diagnostic breathing test (76.4% in 2007 and 82.4% in 2009). Among adults with COPD, 43.0% reported having gone to a physician and 14.9% visited an emergency department (ED) or were admitted to a hospital (2007) for COPD-related symptoms in the previous 12 months. Only 48.1% of persons reported daily use of medications for their COPD (2007). These results indicate that many adults with COPD might not have had adequate diagnostic spirometry, and many who might benefit from daily medications, such as long-acting bronchodilators and inhaled corticosteroids, are not taking them. Continued and expanded surveillance is needed to evaluate the effectiveness of prevention and intervention programs and support efforts to educate the public and physicians about COPD symptoms, diagnosis, and treatment.

BRFSS is a state-based, random-digit—dialed telephone survey of the civilian noninstitutionalized U.S. population aged ≥18 years that is conducted annually by state health departments in collaboration with CDC.\* This report summarizes unique state-specific data collected by the North Carolina Division of Public Health in 2007 and 2009. Council of American Survey and Research Organizations (CASRO) response rates<sup>†</sup> for the state were 55.4% in 2007 and 62.5% in 2009. Cooperation rates<sup>§</sup> were 74.8% in 2007 and 80.5% in 2009.

All respondents were asked, "Have you ever been told by a doctor or health professional that you have COPD, emphysema, or chronic bronchitis?" Respondents who answered "yes" to this question were asked a series of follow-up questions about health-care resource use and quality of life related to their COPD. Crude and age-adjusted (5) prevalence estimates and 95% confidence intervals (CI) were calculated for groups defined by selected characteristics. Statistical significance (p<0.05) was determined by t-test. Follow-up questions were analyzed separately if they were not identical in the 2 years that the COPD module was administered.

Among respondents, 5.7% reported having been told by a health professional that they had COPD, emphysema, or chronic bronchitis (Table). The prevalence of self-reported COPD increased with age, from a low of 3.1% for adults aged 18–44 years, to >10% for adults aged ≥65 years. Respondents with less than a high school diploma were more likely to report COPD (11.1%) than those with a high school diploma (6.7%) or at least some college education (4.2%). No significant differences were observed by sex or race. Current smokers were more likely to report COPD (11.7%) than either former smokers (5.6%) or never smokers (3.0%).

Respondents who reported COPD were less likely to report having no personal doctor or health-care provider (16.0%) than respondents without COPD (23.0%) (Figure). However, persons with COPD were more likely to report cost as an obstacle to medical care (34.0% versus 17.0%), poor or fair health status (46.0% versus 16.0%), or moderate or severe disability

<sup>\*</sup> Additional information about BRFSS is available at http://www.cdc.gov/brfss.

<sup>&</sup>lt;sup>†</sup> The percentage of persons who completed interviews among all eligible persons, including those who were not successfully contacted.

<sup>§</sup> The percentage of persons who completed interviews among all eligible persons who were contacted.

<sup>¶</sup>In 2007, the follow-up COPD module included the following questions: 1) "Have you ever been given a breathing test to diagnose your COPD, chronic bronchitis, or emphysema?" 2) "Would you say that shortness of breath affects the quality of your life?" 3) "Other than a routine visit, have you had to see a doctor in the past 12 months for symptoms related to shortness of breath, bronchitis, or other COPD, or emphysema flare?" 4) "Did you have to visit an emergency room or be admitted to the hospital in the past 12 months because of your COPD, chronic bronchitis, or emphysema?" and 5) "How many different medications do you currently take each day to help with your COPD, chronic bronchitis, or emphysema (categorized as none or at least one medication reported)?" In 2009, the follow-up COPD module included the following questions: 1) "Have you ever been given a breathing test, which measures how much air you can breathe out through a tube, to diagnose your COPD, chronic bronchitis, or emphysema?" 2) "Would you say that shortness of breath affects the quality of your life?" 3) "Other than a routine visit, have you had to see a doctor in the past 12 months for symptoms related to shortness of breath, bronchitis, or other COPD, or emphysema flare?" 4) "During the past 12 months, have you stayed in a hospital overnight because of shortness of breath, COPD, or emphysema flare?" and 5) "Prednisone is a medicine that helps people with breathing problems breathe easier. It is sometimes called Deltasone or Medrol. During the past 12 months, has a doctor ever prescribed prednisone for your breathing problems?"

TABLE. Age-specific and age-adjusted\* percentage of adults reporting having ever been told by a doctor or health professional that they had chronic obstructive pulmonary disease (COPD), emphysema, or chronic bronchitis, by selected characteristics — Behavioral Risk Factor Surveillance System (BRFSS), North Carolina, 2007 and 2009

Characteristic	No. of respondents†	No. with COPD <sup>†</sup>	%	(95% CI)
Total*	26,227	2,187	5.7	(5.3–6.1)
Year*				
2007	13,990	1,195	6.0	(5.5-6.6)
2009	12,237	992	5.4	(4.8-6.0)
Age group (yrs)				
18–44	7,395	256	3.1	(2.5-3.7)
45-54	5,202	361	6.4	(5.3-7.6)
55–64	5,587	570	8.6	(7.7-9.5)
65–74	4,579	608	11.7	(10.6-12.9)
≥75	3,464	392	10.4	(9.1–11.7)
Sex*				
Men	9,622	693	5.3	(4.7-6.1)
Women	16,605	1,494	6.0	(5.5-6.5)

Educational level*				
Less than high school diploma or GED	3,521	547	11.1	(9.4–12.8)
High school diploma or GED	7,766	766	6.7	(5.7-7.6)
At least some college	14,914	873	4.2	(3.7-4.6)
Smoking status*				
Current smoker	5,015	791	11.7	(10.4-13.1)
Former smoker	7,948	877	5.6	(4.9-6.3)
Never smoked	13,175	513	3.0	(2.5-3.5)

 $\label{lem:abbreviations: COPD = chronic obstructive pulmonary disease, which includes emphysema and chronic bronchitis; CI = confidence interval; GED = General Education Development certificate.$ 

(37.0% versus 9.1%), compared with persons without COPD. No statistically significant differences were observed in having health-care coverage based on COPD status.

Among respondents who reported having ever been diagnosed with COPD, 76.4% reported having had a diagnostic breathing test in 2007 and 82.4% in 2009. A doctor's visit for COPD-related symptoms (including shortness of breath, bronchitis, and COPD or emphysema flare) in the past 12 months was reported by 43.0%. More than two thirds of respondents with COPD (70.7%) reported that shortness of breath affected their quality of life. An ED visit or hospital admission for COPD-related symptoms in the past 12 months was reported by 14.9% of respondents with COPD in 2007. In 2009, 13.8% of adults with COPD reported an overnight hospital stay for COPD-related symptoms in the past 12 months. In 2007, 48.1% of respondents with COPD reported use of

at least one daily medication for COPD, and in 2009, 28.7% said they had been prescribed prednisone. Adults who reported a physician visit for COPD symptoms, a visit to an ED or hospital admission for COPD, or impaired quality of life because of COPD symptoms were more likely to be using daily COPD medications compared with those without (56.3% versus 28.0%, 71.7% versus 34.8%, and 48.0% versus 25.5%, respectively). Those adults also were more likely to have been prescribed prednisone compared with those without such reports (50.1% versus 11.4%, 69.5% versus 21.7%, and 33.7% versus 13.9%, respectively).

Among respondents who reported a COPD diagnosis, those aged 18-44 years in 2007 were less likely to report having had a breathing test for the diagnosis of their COPD (59.1%; CI = 44.7% - 73.4%) compared with all other age groups. In 2009, those aged 18-44 years were less likely to report having had a diagnostic breathing test (70.8%; CI = 58.3%-83.3%) compared with those aged 65–74 years (92.0%; CI = 88.5%–95.4%). No significant differences were observed between groups defined by sex, race, educational level, smoking status, health-care coverage status, having a personal physician or health-care provider, restricted access to doctor because of cost, or self-rated health status. In 2007, those who had visited an ED or had been admitted to the hospital because of COPD

were more likely to report a diagnostic breathing test (90.0%; CI = 81.1%–99.0%) compared with those without such a hospital visit (66.8%; CI = 58.3%–75.2%). In 2009, nearly all (99.4%; CI = 98.7%–100.0%) the adults who reported an overnight stay at the hospital for COPD reported a diagnostic breathing test compared with 77.3% (CI = 70.2%–84.3%) of those who did not report an overnight hospital stay. In 2007, 82.9% (CI = 75.6%–90.2%) of adults taking at least one COPD medication daily reported a diagnostic breathing test compared with 61.4% (CI = 51.3%–71.5%) of those not taking any COPD medications.

#### Reported by

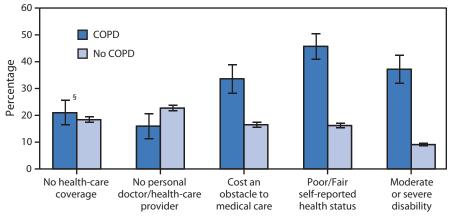

Harry Herrick, MSPH, MSW, MEd, North Carolina State Center for Health Statistics; Roy Pleasants, PharmD, Duke Univ School of Medicine, Durham, North Carolina. Anne G. Wheaton, PhD,

Yong Liu, MD, Earl S. Ford, MD, Letitia R. Presley-Cantrell, PhD, Janet B. Croft, PhD, Div of Population Health, National Center for Chronic Disease Prevention and Health Promotion, CDC. Corresponding contributor: Anne G. Wheaton, awheaton@cdc.gov, 770-488-5362.

#### **Editorial Note**

North Carolina has used the 2007 BRFSS data to identify counties with high COPD prevalence and has implemented public awareness activities for local community and education programs for health-care providers. Most recently, 2007 and 2009 BRFSS data formed the basis for community-based programs that targeted persons with low incomes who used free clinics as their primary source of health care. These programs are taking place through a network of free clinics in North Carolina, South Carolina, and Virginia.

Prevalence of self-reported, physician-diagnosed COPD was 5.7% among adults in North Carolina. More than 20% of respondents with COPD had not been given a breathing test when diagnosed with COPD. Although COPD has no cure, medications are used to improve health status and quality of life by controlling symptoms, reducing the frequency and severity of COPD exacerbations, and improving exercise

tolerance. A significant proportion of persons who likely suffer from more severe COPD, as suggested by physician visits for COPD symptoms, hospital visits for COPD, and impaired quality of life because of shortness of breath, were not using daily medications to control their COPD. This discrepancy might reflect an underuse of medications to control symptoms. Many respondents also indicated that COPD symptoms resulted in physician and hospital visits in the previous 12 months. These results suggest that COPD is not well-controlled in North Carolina.

The prevalence of COPD in this report is similar to national, self-reported data from 1998–2009 (2). The annual average prevalence of COPD in the U.S. Census division that includes North Carolina (South Atlantic) was 5.8% for 2007–2009 (2). However, if spirometry measures are used as the criterion, data from the National Health and Nutrition Examination Survey show that self-reported COPD only identifies half of persons with COPD (6). Therefore, prevalence estimates based on self-report likely are underestimates.

Although most respondents with COPD

reported having been given a breathing test to diagnose their COPD, >20% did not report a diagnostic breathing test. Spirometry is important to distinguish between COPD and other conditions, primarily asthma. The specificity that was added to the breathing test question in 2009 (i.e., "...which measures how much air you can breathe out through a tube...") might have aided respondent recall, resulting in a greater number of respondents reporting having had a breathing test compared with 2007 responses. This has implications for future use of this question. Age-adjustment also affected breathing test rates, because young adults are less likely to have the test. This, in turn, argues for the need for younger adults (18-44 years) with COPD symptoms to have a diagnostic breathing test, particularly because COPD is more difficult to diagnosis in its early stages. Conducting spirometry after administration of a bronchodilator also is helpful in predicting how well a patient will respond to treatment. New clinical practice guidelines from the American College of Physicians (7) recommend that "spirometry should be obtained to diagnose airflow obstruction in patients with respiratory symptoms." These respiratory symptoms include chronic cough, wheezing, sputum production, and shortness of breath. Respondents who had visited a hospital for COPD symptoms in the previous 12

bronchitis.

\* Age-adjusted to the 2000 U.S. standard population aged ≥18 years.

<sup>&</sup>lt;sup>†</sup> Health-care coverage based on response to, "Do you have any kind of health-care coverage, including health insurance, prepaid plans such as HMOs, or government plans such as Medicare?" Personal doctor/health-care provider based on response to, "Do you have one person you think of as your personal doctor or health care provider?" Cost an obstacle to medical care based on response to, "Was there a time in the past 12 months when you needed to see a doctor but could not because of cost?" Health status based on response to, "Would you say that in general your health is — excellent, very good, good, fair, or poor." Disability category based on response to, "A disability can be physical, mental, emotional, or communication related. Do you consider yourself to have a disability?" If yes, respondents were asked, "Would you say your disability is mild, moderate, or severe?"

months were more likely to have had a diagnostic breathing test. Determining whether this finding was a result of breathing tests being administered to persons with more severe symptoms and possibly more advanced COPD was beyond the scope of the survey.

The findings in this report are subject to at least four limitations. First, BRFSS only surveyed households with landline telephones in 2007 and 2009. The proportion of cellular telephone-only households (no landline, but accessible by cellular telephone) has increased substantially in recent years, which results in a larger segment of the younger, single or never married, Hispanic, or unemployed adult populations not being included in landline samples (8). Because COPD is observed more commonly in older populations, this limitation might not be important. Second, institutionalized persons are not surveyed by BRFSS. Because this category includes older persons in nursing facilities, the actual prevalence of COPD in North Carolina might be higher than it was in the BRFSS sample. Third, the response rates (55.4% in 2007 and 62.5% in 2009) also might limit the generalizability of the results if the characteristics of the respondents and nonrespondents differ. Finally, the BRFSS North Carolina estimates are based on self-report and not on physiologic measures, such as spirometry, and thus might underestimate the actual prevalence of COPD and burden of disease.

Although some data on COPD prevalence on a national or regional level are available, only a few states had undertaken efforts to collect COPD prevalence data before 2011. North Carolina was the first to collect data regarding use of diagnostic breathing tests, physician visits, hospital admissions, and use of COPD medications as part of an existing surveillance system. High quality surveillance data are necessary to evaluate the effectiveness of prevention and intervention programs such as the National Heart, Lung, and Blood Institute's "COPD Learn More Breathe Better" campaign\*\* and to improve public and physician awareness of symptoms of COPD, diagnosis, and treatment. In addition to these benefits of expanded surveillance, the public health community can help to reduce the burden of COPD by reducing exposure to environmental tobacco smoke, dust, and other indoor and outdoor air pollutants through tobacco-control and other policies, and by continuing to support and expand smoking cessation programs. Physicians should encourage smoking cessation among all smoking patients. Clinical interventions have been shown to increase motivation to quit and improve abstinence rates (9). Furthermore, smoking cessation decreases the rate in lung function decline among COPD patients (10).

#### What is already known on this topic?

Chronic obstructive pulmonary disease (COPD) is a leading cause of death and disability in the United States, but information on state-specific prevalence has been sparse.

#### What is added by this report?

Among adults in North Carolina, 5.7% reported having been told by a health professional that they had COPD. A majority of persons with COPD had been given a diagnostic breathing test, but less than half were using daily COPD medications.

#### What are the implications for public health practice?

Physicians should conduct spirometry to diagnose COPD and prescribe appropriate medications to control symptoms and reduce exacerbations. Clinicians and the public health community also should support smoking cessation efforts.

## **Announcement**

# National Sleep Awareness Week — March 5–11, 2012

During March 5–11, 2012, National Sleep Awareness Week will be observed in the United States. The National Sleep Foundation recommends that U.S. adults receive, on average, 7–9 hours of sleep per night (*I*); however, 37.1% of adults report regularly sleeping <7 hours per night (*2*).

Persons reporting sleeping <7 hours on average during a 24-hour interval are more likely to report unintentionally falling asleep during the day at least 1 day out of the preceding 30 days (46.2% compared with 33.2%) and nodding off or falling asleep at the wheel during the previous 30 days (7.3% compared with 3.0%) (3). Frequent insufficient sleep (14 or more days in the past 30 days) also has been associated with self-reported anxiety, depressive symptoms, and frequent mental and physical distress (4).

Such findings suggest the need for greater awareness of the importance of sufficient sleep. Further information about factors relevant to optimal sleep can be obtained from the National Sleep Foundation (http://www.sleepfoundation.org) and CDC (http://www.cdc.gov/sleep).

## **Erratum**

### Vol. 61, No. 5

In the QuickGuide supplement, "Recommended Immunization Schedules for Persons Aged 0 Through 18 Years — United States, 2012," an error occurred on page 2, in the second bulleted text in the first footnote regarding hepatitis B vaccination. The bulleted text should read, "For infants born to hepatitis B surface antigen (HBsAg)—positive mothers, administer HepB vaccine and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth. These infants should be tested for HBsAg and antibody to HBsAg (anti-HBs) 1 to 2 months after completion of at least 3 doses of the HepB series, at age 9 through 18 months (generally at the next well-child visit)."

# TABLE I. (Continued) Provisional cases of infrequently reported notifiable diseases (<1,000 cases reported during the preceding year) — United States, week ending February 25, 2012 (8th week)\*

- —: No reported cases. N: Not reportable. NN: Not Nationally Notifiable. Cum: Cumulative year-to-date counts.
- \* Case counts for reporting year 2011 and 2012 are provisional and subject to change. For further information on interpretation of these data, see http://www.cdc.gov/osels/ph\_surveillance/nndss/phs/files/ProvisionalNationa%20NotifiableDiseasesSurveillanceData20100927.pdf.
- † Calculated by summing the incidence counts for the current week, the 2 weeks preceding the current week, and the 2 weeks following the current week, for a total of 5 preceding years. Additional information is available at http://www.cdc.gov/osels/ph\_surveillance/nndss/phs/files/5yearweeklyaverage.pdf.
- Not reportable in all states. Data from states where the condition is not reportable are excluded from this table except starting in 2007 for the arboviral diseases, STD data, TB data, and influenza-associated pediatric mortality, and in 2003 for SARS-CoV. Reporting exceptions are available at http://www.cdc.gov/osels/ph\_surveillance/nndss/phs/infdis.htm.
- Includes both neuroinvasive and nonneuroinvasive. Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (ArboNET Surveillance). Data for West Nile virus are available in Table II.
- \*\* Data for *H. influenzae* (all ages, all serotypes) are available in Table II.
- <sup>††</sup> Updated weekly from reports to the Influenza Division, National Center for Immunization and Respiratory Diseases. Since October 2, 2011, four influenza-associated pediatric deaths occurring during the 2011-12 influenza season have been reported.
- §§ No measles cases were reported for the current week.
- ¶ Data for meningococcal disease (all serogroups) are available in Table II.
- \*\*\* CDC discontinued reporting of individual confirmed and probable cases of 2009 pandemic influenza A (H1N1) virus infections on July 24, 2009. During 2009, four cases of human infection with novel influenza A viruses, different from the 2009 pandemic influenza A (H1N1) strain, were reported to CDC. The four cases of novel influenza A virus infection reported to CDC during 2010, and the eight cases reported during 2011, were identified as swine influenza A (H3N2) virus and are unrelated to the 2009 pandemic influenza A (H1N1) virus. Total case counts are provided by the Influenza Division, National Center for Immunization and Respiratory Diseases (NCIRD).
- ††† No rubella cases were reported for the current week.
- 555 Updated weekly from reports to the Division of STD Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention.
- 👭 There were no cases of viral hemorrhagic fever reported during the current week. See Table II for dengue hemorrhagic fever

FIGURE I. Selected notifiable disease reports, United States, comparison of provisional 4-week totals February 25, 2012, with historical data

<sup>\*</sup> No measles cases were reported for the current 4-week period yielding a ratio for week 8 of zero (0).

C.N.M.I.: Commonwealth of Northern Mariana Islands.
U: Unavailable. —: No reported cases. N: Not reportable. NN: Not Nationally Notifiable. Cum: Cumulative year-to-date counts. Med: Median. Max: Maximum.

\* Case counts for reporting year 2011 and 2012 are provisional and subject to change. For further information on interpretation of these data, see http://www.cdc.gov/osels/ph\_surveillance/nndss/phs/files/ProvisionalNationa%20NotifiableDiseasesSurveillanceData20100927.pdf. Data for TB are displayed in Table IV, which appears quarterly.

<sup>†</sup> Data for *H. influenzae* (age <5 yrs for serotype b, nonserotype b, and unknown serotype) are available in Table I.

C.N.M.I.: Commonwealth of Northern Mariana Islands.
U: Unavailable. —: No reported cases. N: Not reportable. NN: Not Nationally Notifiable. Cum: Cumulative year-to-date counts. Med: Median. Max: Maximum.

\* Case counts for reporting year 2011 and 2012 are provisional and subject to change. For further information on interpretation of these data, see http://www.cdc.gov/osels/ph\_surveillance/nndss/phs/files/ProvisionalNationa%20NotifiableDiseasesSurveillanceData20100927.pdf. Data for TB are displayed in Table IV, which appears quarterly.

† Data for meningococcal disease, invasive caused by serogroups A, C, Y, and W-135; serogroup B; other serogroup; and unknown serogroup are available in Table I.

C.N.M.I.: Commonwealth of Northern Mariana Islands.
U: Unavailable. —: No reported cases. N: Not reportable. NN: Not Nationally Notifiable. Cum: Cumulative year-to-date counts. Med: Median. Max: Maximum.

\* Case counts for reporting year 2011 and 2012 are provisional and subject to change. For further information on interpretation of these data, see http://www.cdc.gov/osels/ph\_surveillance/nndss/phs/files/ProvisionalNationa%20NotifiableDiseasesSurveillanceData20100927.pdf. Data for TB are displayed in Table IV, which appears quarterly.

† Includes drug resistant and susceptible cases of invasive Streptococcus pneumoniae disease among children <5 years and among all ages. Case definition: Isolation of S. pneumoniae from a normally sterile body site (e.g., blood or cerebrospinal fluid).

C.N.M.I.: Commonwealth of Northern Mariana Islands.

U: Unavailable. —: No reported cases. N: Not reportable. NN: Not Nationally Notifiable. Cum: Cumulative year-to-date counts. Med: Median. Max: Maximum.

<sup>\*</sup> Case counts for reporting year 2011 and 2012 are provisional and subject to change. For further information on interpretation of these data, see http://www.cdc.gov/osels/ph\_surveillance/

ndss/phs/files/ProvisionalNationa%20NotifiableDiseasesSurveillanceData20100927.pdf. Data for TB are displayed in Table IV, which appears quarterly.

† Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (ArboNET Surveillance). Data for California serogroup, eastern equine, Powassan, St. Louis, and western equine diseases are available in Table I.

§ Not reportable in all states. Data from states where the condition is not reportable are excluded from this table, except starting in 2007 for the domestic arboviral diseases and influenza-

associated pediatric mortality, and in 2003 for SARS-CoV. Reporting exceptions are available at http://www.cdc.gov/ncphi/disss/nndss/phs/infdis.htm.

U: Unavailable. —: No reported cases.

Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of >100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

<sup>†</sup> Pneumonia and influenza.

<sup>§</sup> Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks. ¶ Total includes unknown ages.

#### Morbidity and Mortality Weekly Report

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format. To receive an electronic copy each week, visit MMWR's free subscription page at http://www.cdc.gov/mmwr/mmwrsubscribe. html. Paper copy subscriptions are available through the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data presented by the Notifiable Disease Data Team and 122 Cities Mortality Data Team in the weekly MMWR are provisional, based on weekly reports to CDC by state health departments. Address all inquiries about the MMWR Series, including material to be considered for publication, to Editor, MMWR Series, Mailstop E-90, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333 or to mmurq@cdc.gov.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

References to non-CDC sites on the Internet are provided as a service to MMWR readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of these sites. URL addresses listed in MMWR were current as of the date of publication.
