#### Introduction and background

A previous report of the National Center for Health Statistics (NCHS) emphasized the level of firearm mortality among children and youth (1). The report showed that in 1987, 11 percent of deaths among children and youth aged 1-19 years resulted from firearm use. In addition, in a recent paper (2) the homicide rate for young males 15-24 years of age in the United States was compared with rates in 21 industrialized countries. Not only was the U.S. homicide rate 4 to 70 times the homicide rates in other countries, but three-fourths of these homicides in the United States were committed with firearms, compared with less than one-fourth in the other countries.

Furthermore, the need to reduce the level of violent deaths among teenagers (15-19 year olds) and young adults in the United States is the focus of several of the Year 2000 Objectives for the Nation (3). Specifically, reductions are targeted for: the homicide rate for all persons, with special targets set for children 3 years of age and under, for black males and females ages 15-34 years and for Hispanic males ages 15-34 years; the suicide rate for all persons, with special targets set for young persons 15-19 years of age, and for males 20-34 years of age; and the weapon-related violent death rate for all persons.

Although the previous firearm mortality report was limited to children ages 1–19 years, this report extends the age groups to those 20–34 years of age in order to include those ages where the risk of homicide, and, in particular, of firearm-related homicide, is greatest (figure 1). In 1988, 77 percent of homicides among teenagers 15–19 years of age were associated with firearm use (88 percent among black males); at 20–24 years of age, 70 percent of homicides resulted from firearm use (81 percent among

black males); at 25–29 years of age, 68 percent were firearm related (75 percent among black males); and at 30–34 years of age, 64 percent (70 percent among black males) were caused by firearm use.

Suicide rates follow an age pattern different from homicide rates; death rates are fairly constant at ages 20–64 years, and peak for the older population age groups (figure 2). The agespecific proportions of suicides resulting from firearm use are lower than the proportions of homicides, averaging 53–61 percent of suicides at 10–14 years of age through 30–34 years of age.

The purpose of this report is to update and expand the previous report on firearm mortality (1), focusing on firearm deaths associated with homicide, suicide, and unintentional injury (used synonymously with the term "accident" as defined in the International Classification of Diseases) among children, youth, and young adults ages 1–34 years.

The analysis of firearm mortality for persons 15–34 years of age concentrates on males although the analysis for persons 1–14 years of age is for each sex. The emphasis on males at the older ages is because firearm death

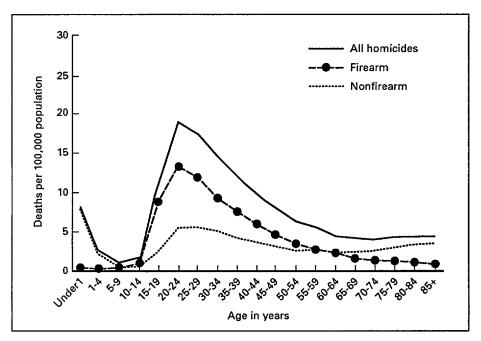

Figure 1. Death rates due to homicide, by age and firearm status: United States, 1988

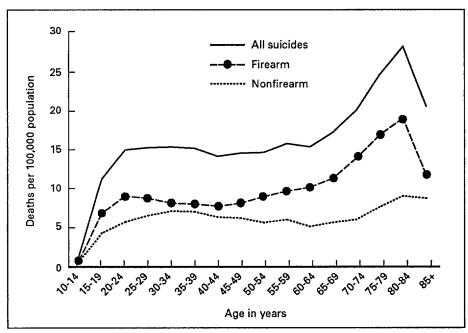

Figure 2. Death rates due to suicide, by age and firearm status: United States, 1988

rates for black and white males in each age group substantially exceed the respective rates for black and white females. Particularly high mortality sex ratios in firearm mortality are evident at 15–19 years of age through 30–34 years of age. For white persons, male firearm death rates are 5–7 times rates for females and for black persons, male firearm death rates are 6–9 times rates for females.

#### Results

To gain perspective on the magnitude of firearm mortality among this country's youth, it is instructive to compare trends in firearm mortality among teenage males with those in mortality associated with natural causes of death, that is, with diseases rather than with injuries or violence (figure 3). For black males 15–19 years of age, the firearm death rate in

1979 was 1.5 times the death rate from natural causes. A decade earlier, the two rates were nearly identical. Between 1979 and 1988, the natural causes death rate was relatively stable.

The trend in firearm mortality among black males 15–19 years of age, however, has been quite different. From 1980 to 1984, the firearm death rate declined 21 percent to 35.8 firearm deaths per 100,000 population. In 1984, the firearm death rate was 1.4 times the natural causes death rate. From 1984 to 1988, the firearm death rate for black males more than doubled at an annual rate of 18.6 percent to 79.5 per 100,000. Thus, by 1988, the firearm death rate for black teenage males was 2.8 times the rate for natural causes of death.

For white males 15–19 years of age, the natural causes death rate in 1979 was 11 percent higher than the firearm death rate. A decade earlier, the natural causes death rate was 2.6 times the firearm death rate. During the 1980's, the natural causes death rate for white teenage males varied little, from 19–22 deaths per 100,000 population. Firearm mortality has shown somewhat more variation, and, in 1988, the firearm death rate exceeded the natural causes death rate for the first time (by 11 percent).

#### **Current status**

In 1988, 17,249 firearm deaths occurred among persons 1-34 years of age. This represented 15 percent of all deaths at those ages. Nearly 4,000 firearm deaths were among children 1-19 years of age, accounting for 12 percent of all deaths in that age group. Of those firearm deaths, about 3,200 were among teenagers 15-19 years of age, accounting for 20 percent of all teenage deaths. At ages 20-24 years, 21 percent of all deaths resulted from firearm use; 18 percent of all deaths at ages 25-29 years, and 12 percent of all deaths at ages 30-34 years resulted from firearm use.

Variation by race and sex within age groups is large, especially for teenagers ages 15-19 years (figure 4). Among black teenage males, 48 percent of the deaths were firearm-related, compared with 18 percent

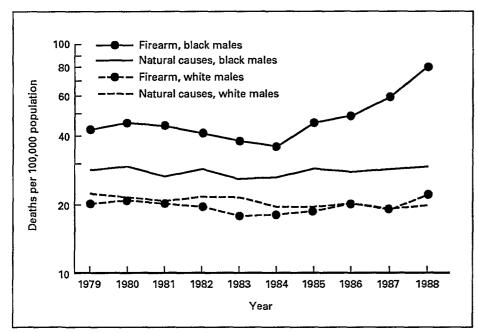

Figure 3. Death rates due to firearms and natural causes, for white and black males aged 15-19 years: United States, 1979-88

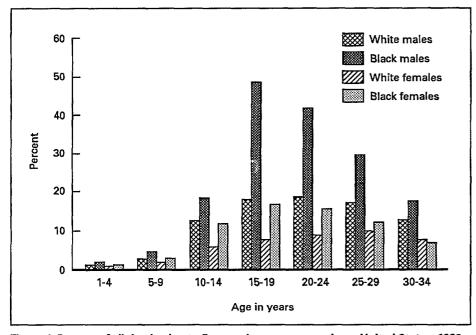

Figure 4. Percent of all deaths due to firearms by age, race, and sex: United States, 1988

among white teenage males. Among black females, 17 percent of deaths resulted from firearm use, compared with 8 percent among white females. Among white males 20–24 years of age through 25–29 years of age, 17–19 percent of deaths were caused by firearm use, compared with 30–42 percent among black males. Among females, firearm deaths accounted for

6-17 percent of all deaths at 10-14 years of age through 30-34 years of age, with percentages among black females exceeding those for white females except at ages 30-34 years.

The risk of firearm death rises until the young adult years and then declines. In 1988, the firearm death rate increased from less than 1 per 100,000 population at ages 1-4 years

and 5-9 years, to 3.1 at ages 10-14 years, to 17.7 at ages 15-19 years, peaking at 23.9 at ages 20-24 years and declining to 21.6 and 18.3 at ages 25-29 years and 30-34 years, respectively (figure 5 and table 1).

The manner of firearm deaths varies by age. Among the youngest children, those 1-9 years of age, homicide accounted for 56 percent and unintentional firearm injuries for 43 percent of the firearm deaths in 1988. At ages 10-14 years, homicide and unintentional firearm injuries each accounted for about 35 percent, suicide for 24 percent, and intent unknown for 6 percent of the firearm deaths. (At all other ages, intent unknown accounted for 1-2 percent of the firearm deaths.) At 15–19 years of age through 30–34 years of age, homicides accounted for 51-56 percent of firearm deaths (82-87 percent among black males), and suicides accounted for 38-45 percent of firearm deaths (58-60 percent among white males).

The overall age patterns in firearm mortality among white and black males are similar. However, within each age group the risk of firearm death is strongly associated with race. Firearm mortality race ratios (black compared with white) average 2–3:1 for males ages 1–14 years and for females through ages 30–34 years, although for males 15–19 years of age through 30–34 years of age, race ratios are closer to 4:1.

For children 1–9 years of age, firearm homicide rates for black males were four times the rates for white males; race ratios were smaller for females 1–9 years of age (2–3:1). Unintentional firearm injury death rates were twice as high for black males ages 1–4 years and 5–9 years as for white males. Death rates were lower and differences were smaller for females 1–9 years of age.

At ages 10-14 years, black males were more than five times as likely as white males to have been firearm homicide victims (4.5 compared with 0.8 deaths per 100,000 population); white males were more apt to have died from firearm suicides, 1.2 compared with 0.7 deaths per 100,000

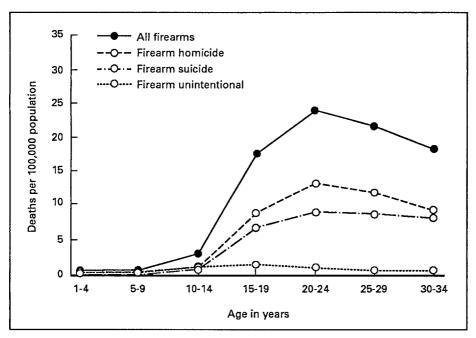

Figure 5. Firearm death rates by manner of death and age, for persons 1-34 years: United States, 1988

population. Although the firearm homicide rates were much lower for females ages 10–14 years, race differences in firearm homicides were about as high for females as for males. Race differences in unintentional firearm mortality were smaller than for homicide; the rate for black males 10–14 years of age was 1.2 times that for white males, 2.1 compared with 1.8 firearm deaths per 100,000. Although the unintentional firearm death rates were considerably lower for females 10–14 years of age, race differences were larger than among males, 2:1.

For black males 15–19 years of age, the firearm homicide rate was more than 11 times the rate for white males, 67.9 compared with 6.0 per 100,000 population. In contrast, the firearm suicide rate was nearly twice as high for white male as for black male teenagers, 12.7 compared with 6.8 per 100,000 population.

At 20-24 years of age through 30-34 years of age, black male firearm homicide rates were 8-10 times those for white males. Race differences (white compared with black) in firearm suicide rates at these ages were considerably smaller, less than 2:1.

#### Trends (tables 1 and 2)

Consistent with earlier patterns (1), there was virtually no change from 1987 to 1988 in the overall firearm death rate for young children 1-4 or 5-9 years of age. For children ages 10-14 years, however, 1988 was the second consecutive year of a small increase in the firearm death rate, with the rate rising to its highest level, 3.1 firearm deaths per 100,000. In this age group, the greatest change occurred for black females for whom the firearm death rate more than doubled from 1.4 to 3.6 firearm deaths per 100,000.

From 1979 to 1984, the firearm death rate for teenagers 15-19 years of age decreased 11 percent to 12.4 per 100,000. After 1984, however, the death rate increased 43 percent, rising 20 percent in 1988 to 17.7 deaths per 100,000, the highest level to date. These recent increases were concentrated among black males, for whom both the firearm death rate and the firearm homicide rate more than doubled. The most recent increase, from 1987 to 1988, has been the largest single year increase in the firearm death rate for black male teenagers-35 percent (figure 6). Although the risk of firearm suicide is relatively low

(compared with homicide) among black males, the rate doubled from 1984 to 1988.

For white male teenagers, the firearm death rate increased by 22 percent from 1984 to 1988, by 18 percent for firearm homicides, and by 31 percent for firearm suicides.

From 1979 to 1985, the firearm death rate for persons 20-24 years of age decreased 17 percent. During the next 3 years, the rate increased 16 percent to 23.9 per 100,000 in 1988. For black males 20–24 years of age, the firearm death rate decreased 33 percent from 1980 to 1984, followed by a 59 percent increase between 1984 and 1988 to 119.2 firearm deaths per 100,000 population, the highest level since 1979 (although still lower than during the early 1970's). Nearly 9 in 10 firearm deaths among these black males were associated with homicides. Although relatively few firearm deaths were suicides, the death rate from this cause increased 46 percent from 1984 to 1988 to 12.3 deaths per 100,000 population (similar to the level in 1979).

For white males ages 20–24 years, the firearm death rate decreased from a high of 35.3 per 100,000 in 1980 to a low of 28.7 in 1983 and remained relatively unchanged at about 30 per 100,000 through 1988. The firearm homicide rate for this group was also relatively unchanged from 1983 to 1988; in 1988, the rate was 26 percent lower than the rate in 1980. The firearm suicide rate remained practically unchanged from 1979 to 1988 at about 17 per 100,000.

For white females ages 20-24 years, the firearm death rate decreased by 32 percent from 1979 to 1988. For black females, the firearm death rate decreased from 17.4 in 1979 to 10.3 in 1985, but then increased 35 percent to 13.9 per 100,000 in 1988.

From 1979 to 1988 at ages 25–29 years and 30–34 years, firearm mortality decreased by 12–14 percent. For these black males, firearm death rates decreased by about 35–40 percent from 1980 to 1985, paralleling the decline noted for black males 20–24 years of age. Since then, the rate for those aged 25–29 years has fluctuated

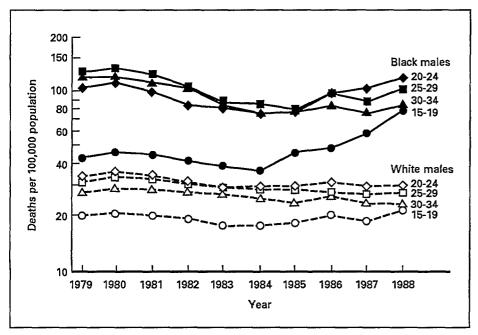

Figure 6. Firearm death rates by age, for white and black males aged 15-34 years: United States, 1979-88

widely, between 87 and 103 per 100,000, but has remained below the 1982 level. At ages 30–34 years, the rate has remained relatively stable in recent years. For this group, the firearm death rate in 1988 was 18 percent lower than in 1982.

Similar to the younger age groups for black males, firearm homicide rates for those 25–29 years of age and 30–34 years of age declined during the first half of the 1980's. However, unlike the rates for those 20–24 years of age, firearm homicide rates decreased between 1986 and 1987. In 1988, the rate for black males 25–29 years of age increased 22 percent to 89.5 per 100,000 (similar to the rate in 1982). For those 30–34 years of age, the 1988 rate was 10 percent higher than the year before (and similar to the rate in 1983).

From 1979 to 1988, firearm death rates for white males ages 25–29 years have been similar to or somewhat lower than rates for those 20–24 years of age (figure 6). Similarly, for white males ages 30–34 years, the trend in the firearm death rate was similar to that for the two younger age groups; however, the death rates were usually 10–15 percent lower than for those ages 25–29 years. In 1988, the firearm

death rates for white males 25–29 years of age and 30–34 years of age were 17–18 percent lower than in 1980.

Firearm suicide rates for white males 25–29 years of age and 30–34 years of age generally remained at about 15–16 and 14–15 per 100,000, respectively, from 1979–88. However, firearm homicide rates have decreased in both of these age groups by 30 and 35 percent, respectively, from 1980 to 1988.

The recent increases noted in firearm homicide mortality, especially among males 15–19 and 20–24 years of age, are not evident in nonfirearm homicide mortality. For males 15–19 years of age, the nonfirearm homicide rate averaged 10–11 per 100,000 for black teenagers and 2 per 100,000 for white teenagers during the period 1984–88. Also during this time, at ages 20–24 years, the rate for white males remained at 5 per 100,000 and for black males, at 21–25 per 100,000.

Nonfirearm suicide rates increased for white teenagers during the decade, paralleling the increase associated with firearms. For white male teenagers 15–19 years of age, the nonfirearm suicide rate increased 33 percent from 5.2 per 100,000 in 1983 to

6.9 per 100,000 in 1988. However, the firearm rate was about twice the non-firearm rate.

For white female teenagers, the nonfirearm suicide rate in 1988 (2.5 per 100,000), although similar to the rate in 1987, was about twice what it was in 1982. For this group, the firearm suicide rate varied little between 1979 and 1988, ranging from 1.7 in 1979 to 2.3 in 1988.

#### Summary

Firearm mortality among children 1–14 years of age has, with one exception, been relatively stable during the past decade. For black females 10–14 years of age, the firearm death rate more than doubled between 1987 and 1988. This increase accounted for about 30 percent of the increase in the death rate for all causes for this group of children. Among persons 25–34 years of age, firearm mortality decreased during the decade.

Among young persons 15–24 years of age, firearm mortality has increased substantially since 1984. In particular, the homicide rate associated with firearms for black males ages 15–19 years more than doubled by 1988. Further, for young black males ages 20–24 years, the firearm homicide rate in 1988 was 1.6 times what it was in 1984.

Thus, in 1988, firearms accounted for 20 percent of all deaths among young persons 15–24 years of age. Among black males ages 15–24 years, 44 percent of all deaths resulted from firearms. In 1988, there were 2.7 million black males ages 15–24 years in the United States; 2,700, or 1 out of every 1,000, died as a result of an incident involving a firearm.

#### **Technical notes**

#### Nature and sources of data

Data shown in this report are based on information from all death certificates filed in the 50 States and the District of Columbia.

Mortality statistics are based on information coded by the National Center for Health Statistics (NCHS) from copies of the original death certificates received from the State registration offices, and on State-coded data provided to NCHS through the Vital Statistics Cooperative Program.

Data for the United States refer to events occurring within the United States.

#### Cause-of-death classification

The mortality statistics presented in this report were compiled in accordance with the World Health Organization regulations, which specify that member nations classify causes of death by the current Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death (4). In this report, causes of death for 1979–88 were classified according to the Ninth Revision of the ICD (ICD-9).

Homicides are classified according to ICD-9 Nos. E960-E969 (Homicide and injury purposely inflicted by other persons) and Nos. E970-E978 (Legal intervention). Homicides caused by firearms are classified under ICD9, Nos. E965.0-E965.4, Assault by firearms. Suicides are classified according to ICD-9 Nos. E950-E959. Suicides caused by firearms are classified under ICD-9 Nos. E955.0-E955.4. Unintentional firearm deaths are classified under ICD-9, No. E922 (Accident

caused by firearm missile). When it is undetermined whether injury deaths by firearms were accidentally or purposely inflicted the deaths are classified under ICD-9, Nos. E985.0-E985.4.

### Population bases for computing rates

The U.S. Bureau of the Census provided the populations used for computing rates shown in this report, represent the population residing in the United States. The estimates are based on census counts, modified by race for 1980 and later years to be consistent with the U.S. Office of Management and Budget categories and historic categories for mortality data. Rates for 1984-88 are not strictly comparable with those of previous years because of new estimation procedures for net migration and net undocumented immigration. Population estimates are described in greater detail in the Technical Appendix of the Monthly Vital Statistics Report Advance Report of Final Mortality Statistics, 1988 (5).

#### Random variation

Although the mortality data in this report (except data for 1972) are not subject to sampling error, they may be affected by random variation in the number of deaths involved. When the number of events is small (perhaps less than 100) and the probability of such an event is small, considerable caution must be observed in interpreting the data. Such infrequent events may be

assumed to follow a Poisson probability distribution. For this distribution, a simple approximation may be used to estimate the confidence interval, as follows:

If N is the number of registered deaths in the population and R is the corresponding rate, the chances are 19 in 20 (approximate 95-percent confidence interval) that

1. 
$$N=2\sqrt{N}$$
 and  $N+2\sqrt{N}$ 

cover the "true" number of events.

2. 
$$R-2\frac{R}{\sqrt{N}}$$
 and  $R+2\frac{R}{\sqrt{N}}$ 

cover the "true" rate.

If the rate  $R_1$  corresponding to  $N_1$  events is compared with the rate  $R_2$  corresponding to  $N_2$  events, the difference between the two rates may be regarded as statistically significant if it exceeds

$$2\sqrt{\frac{R_1^2}{N_1} + \frac{R_2^2}{N_2}}$$

Additional information on random variation may be found in the Technical Appendix of *Vital Statistics of the United States*, 1987 Volume II, Mortality, Part A.

#### Rates of change

Annual rates of change are represented by the slope of a least squares regression line through the logarithm of the annual rates.
