

U.S. Decennial Life Tables for 1999–2001, United States Life Tables

by Elizabeth Arias, Ph.D.; Lester R. Curtin, Ph.D.; Rong Wei, Ph.D.; and Robert N. Anderson, Ph.D.

This report was updated to correct calculation errors in [Tables 1–13](#).

Abstract

Objectives—This report presents period life tables for the United States based on age-specific death rates for the period 1999–2001. These tables are the most recent in a 100-year series of decennial life tables for the United States.

Methods—This report presents complete life tables by age, race (white and black), and sex. Also presented are standard errors of the probability of dying and life expectancy. The data used to prepare these life tables are population estimates based on the 2000 decennial census, deaths occurring in the United States to U.S. residents in the 3 years 1999–2001, counts of U.S. resident births in the years 1997–2001, and population and death counts from the Medicare program for years 1999–2001.

Results—In 1999–2001, life expectancy at birth was 76.86 years for the total U.S. population, representing an increase of 27.62 years from a life expectancy of 49.24 years in 1900. Between 1900 and 2000, life expectancy increased by 40.12 years for black females (from 35.04 to 75.16), by 35.63 years for black males (from 32.54 to 68.17), by 28.91 years for white females (from 51.08 to 79.99), and by 26.55 years for white males (from 48.23 to 74.78).

Introduction

The life tables presented in this report are the most recent in a series of decennial life tables for the United States that dates to the beginning of the 20th century. The 1999–2001 life tables are the 11th in the decennial series. The reporting of deaths at the national level began in 1900 with 10 states and the District of Columbia. As the quality of the reporting improved, states were added to the death-registration area. Beginning with the period 1929–1931, the decennial life tables were produced using data for all of the coterminous United States. Alaska and Hawaii were included beginning with the 1959–1961 decennial life tables. Each set of life tables is based on population data from a decennial census and reported deaths of the 3-year period surrounding the census year (the census year is the

middle year in all but the first in the series, in which deaths for 1900–1902 were used because death reports for 1899 were not collected (1)). The decennial life tables differ in one main respect from the life tables prepared and published annually in the Centers for Disease Control and Prevention's National Center for Health Statistics' (NCHS) *National Vital Statistics Reports*. The annual tables are based on deaths in a single year and, except for census years, on postcensal population estimates rather than on the data from a decennial census.

This report is the first of a series of reports containing life tables for 1999–2001 and other information related to the decennial life table program. Also included in the series is a methodological report that describes in detail the methods employed to estimate the national life tables, a report on national life tables analyzed by major groups of causes of death, and a report containing life tables for individual states and the District of Columbia, including a description of the methods used to estimate individual state life tables.

Data and Methods

Mortality rates for a specific period may be summarized by the life table method to obtain measures of comparative longevity. There are two types of life tables—the cohort (or generation) life table and the period (or current) life table. The cohort life table provides a longitudinal perspective in that it follows the mortality experience of an actual cohort—for example, all persons born in the year 1945—from the moment of birth through consecutive ages in successive years. On the basis of age-specific death rates observed during consecutive years, the cohort life table reflects the mortality experience of a cohort from birth until no lives remain in the group. To prepare just a single complete cohort life table requires data over many years. Constructing cohort life tables entirely on the basis of observed data for real cohorts is usually not feasible because of data unavailability or incompleteness (2–4).

In contrast, the period life table does not represent the mortality experience of an actual birth cohort. Rather, the period life table

presents what would happen to a hypothetical cohort if it experienced throughout its entire life the mortality conditions of a particular period of relatively short duration (often 1 to 3 years). For example, the period life tables for 1999–2001 are based on the assumption that a hypothetical birth cohort will be subject throughout its lifetime to the age-specific death rates prevailing for the actual population in 1999–2001. The period life table may be characterized as rendering a “snapshot” of current mortality experience and shows the long-range implications of a set of age-specific death rates that prevailed at a particular point in time. The life tables presented in this report are period life tables based on age-specific death rates for the period 1999–2001.

The data used to prepare the U.S. decennial life tables for 1999–2001 include deaths occurring in the United States to residents of the United States in the 3 years 1999–2001. The data are classified by age at death, age-specific population estimates for census year 2000, reported number of births for each of the years 1997–2001, and single-year population and death counts for those aged 66–100 years from the Medicare program of the Centers for Medicare and Medicaid Services for the years 1999–2001.

The census population counts used to estimate the life tables shown in this report were produced under a collaborative agreement with the U.S. Census Bureau. Reflecting the new guidelines issued in 1997 by the Office of Management and Budget (OMB), the 2000 census included an option for individuals to report more than one race as appropriate for themselves and household members (5). The 1997 OMB guidelines also provided for the reporting of Asian persons separately from Native Hawaiians or Other Pacific Islanders (NHOPI). Under the prior OMB standards (issued in 1977), data for Asian or Pacific Islander (API) persons were collected as a single group (6). Death certificates filed in state vital statistics offices for the years 1999–2001 included only one race for the decedent in the same categories as specified in the 1977 OMB guidelines, which also called for the grouping of Asians and NHOPI. Death certificate data by race were therefore incompatible with the population data collected in the 2000 census. As a result, NCHS developed a bridging algorithm that bridges reported 2000 decennial population data for multiple-race persons back to single-race categories and that groups API consistent with the 1977 OMB race categories (7).

Certain other data adjustments were necessary prior to the construction of the life tables. In accordance with standard practice, deaths for which age was not stated were allocated proportionally among the various age groups. Similarly, graduation techniques were used to eliminate anomalies arising from random variation and problems with age reporting in vital statistics and census data. Thus, to estimate the complete 1999–2001 life tables, Beer’s minimized fifth-difference procedure was employed to interpolate single-year-of-age number of deaths and population counts from 5-year age intervals (2). Death rates at ages 95 years and over, where the data from the census and from registered deaths are suspect because the accuracy of the reporting of age is not as good as at younger ages, are based on data from the Medicare program. To obtain a smooth transition between vital statistics and Medicare-based rates, the rates from the two sources are blended for ages 66–94 years.

These life tables are based on a complete count of resident deaths in the United States during the 3 years 1999, 2000, and 2001. As such, they are not subject to sampling error. However, even complete counts may be considered as one of a large series of possible results that could

have arisen under the same circumstances. This type of variation is known as random error. The reader should remember that the standard errors shown in this report reflect only this random error. Other errors, such as misreporting age on death certificates or in the census, are not reflected in them.

The probabilities of dying and the expectation of life presented in the report are “point” estimates. They do not give the reader an indication of how accurate they are. Therefore, standard errors of these two estimates are also presented. These can be used to develop confidence intervals within which the parameters are believed to lie. Standard errors of the probability of dying contain six decimal places, and standard errors of life expectancy contain three; they are shown in [Tables 10](#) and [11](#). In both cases, the standard errors contain one place more than the corresponding variable in the life tables. In computing confidence intervals, the limits are rounded to the same number of decimal places that the variable has in the life table.

To obtain a confidence interval around a point estimate, one would add and subtract from the estimated point estimate the product of the standard z-value corresponding to the desired confidence probability and the standard error of the point estimate. For example, a 95% confidence interval for the probability that a black female will die before reaching her 61st birthday is $0.01283 - (1.96 \times 0.000179)$ and $0.01283 + (1.96 \times 0.000179)$ (from [Table 10](#)). The resulting 95% confidence interval ranges from 0.01248 to 0.01318. Likewise, to obtain a 95% confidence interval around the life expectancy of a 60-year-old black female, one would add and subtract the product of the standard z-value (1.96) and the standard error of the point estimate (0.017) (from [Table 11](#)) to life expectancy at 60 years of age (21.20 years). The 95% confidence interval in this case is from 21.17 to 21.23 years. The standard errors and confidence intervals are relatively small because of the large number of deaths in the combined 3 years of data 1999–2001.

Expectation of life—The life table provides a convenient tool for comparing the longevity of different populations or of different subdivisions of a population. The most commonly used measure of longevity is life expectancy (e_x), which is the average number of years of life remaining for persons who have attained a given age (x). Life expectancy and other life table values for each age in the 1999–2001 period are shown for the total population and by race and sex in [Tables 1–9](#). On the basis of the mortality experience of the U.S. resident population in 1999–2001, life expectancy at birth (e_0) was 76.86 years for the total population.

Survivors to specified ages—Another way of estimating the longevity of the hypothetical life table cohort is by determining the proportion who survive to specified ages. The l_x column of the life table provides the data to estimate the proportion. For example, 50,885 persons out of the original life table cohort of 100,000 were alive at exactly 80 years of age (or 50.9%). Thus, the probability that a person will survive from birth to 80 years of age, given 1999–2001 age-specific mortality, is approximately 51%. Probabilities of survival can be calculated at any age by simply dividing the number of survivors at the terminal age by the number at the beginning age. For example, to calculate the probability of surviving from ages 20 to 85 years, one would divide the number of survivors at 85 years of age (34,515) by the number of survivors at 20 years of age (98,664), which results in a 35.0% probability of survival.

Explanation of the columns of the life table

Column 1—Age (x to $x + n$)—This column shows the age interval between the two exact ages indicated. For instance, “7–28” days means the 21-day interval between the exact ages of 7 days and 28 days, and “43–44” years means the interval of 1 year between the 43rd and 44th birthdays. In the life tables in this report, the age interval is always 1 year, except in the case of subdivisions of the first year of life (Table 1).

Column 2—Probability of dying (${}_nq_x$)—This column shows the probability of dying between the beginning of an age interval and before reaching the end of that age interval on the basis of the mortality rates of 1999–2001. For example, for black males, the probability of dying between the 1st and 7th day of life is 0.00186 (Table 8). In other words, for every 1,000 black male babies surviving to day 1 of life, 1.86 of them will die before reaching the 7th day of life. Similarly, for black males in the age interval 20–21 years, the probability of dying is 0.00208, which translates to 2.08 of every 1,000 black males who reach their 20th birthday dying before reaching their 21st birthday. When the age interval is 1 year, the symbol q_x (instead of ${}_1q_x$) is generally used for the probability of dying.

Column 3—Number surviving (l_x)—This column shows the number of persons from the original life table cohort of 100,000 live births who survive to the beginning of each age interval. The l_x values are computed from the ${}_nq_x$ values, which are successively applied to the remainder of the original 100,000 persons still alive at the beginning of each age interval. Thus, out of 100,000 white female babies born alive, 99,488 will complete the first year of life and enter the second; 99,319 will reach age 10; 99,049 will reach age 20; 42,848 will live to age 85; and, 13 will live to age 109 (Table 6).

Column 4—Number dying (${}_nd_x$)—This column shows the number dying in each successive age interval out of the original 100,000 live births. For example, out of 100,000 males born alive, 298 will die in the first day of life, 126 will die between ages 20 and 21 years, and 235 will die between ages 100 and 101 years (Table 2). Each figure in column 4 is the difference between two successive figures in column 3. When the age interval is 1 year, the symbol d_x (instead of ${}_1d_x$) is generally used for the number dying.

Column 5—Person-years lived (${}_nL_x$)—This column shows the number of person-years lived by the life table cohort within an age interval x to $x + n$. Each figure in column 5 represents the total time (in days or years) lived between two indicated birthdays by all those reaching the earlier birthday. Thus, the figure 98,893 for females in the age interval 20–21 years is the total number of years lived between the 20th and 21st birthdays by the 98,915 (column 3) females who reached their 20th birthday out of 100,000 females born alive (Table 3). When the age interval is 1 year, the symbol L_x is generally used instead of ${}_1L_x$.

Column 6—Total number of person-years lived (T_x). This column shows the total number of person-years that would be lived after the beginning of the age interval x to $x + n$ by the life table cohort. For example, the figure 7,847,649 is the total number of years lived after attaining 1 year of age by the 99,375 females reaching that age (Table 3).

Column 7—Expectation of life (e_x)—The expectation of life at any given age is the average number of years remaining to be lived by those surviving to that age on the basis of a given set of age-specific rates of dying. It is derived by dividing the total person-years that would be

lived above age x by the number of persons who survived to that age interval (T_x/l_x). Thus, the average remaining lifetime for black males who reach age 1 year is 68.25 years (6,718,317 divided by 98,437) (Table 8).

The expectation of life at birth (e_0) is strongly affected by the number of deaths occurring during the first year of life. In comparing the longevity of different populations, also considering expectation of life at 1 year of age (e_1) may be desirable because this measure is not affected by the infant mortality rate. When infant mortality is high, life expectancy at 1 year of age is higher than at birth. This is a unique situation. At all other ages, life expectancy declines with advancing age. For the black population, life expectancy at 1 year of age has been greater than life expectancy at birth in all previous decennial life tables. In 1999–2001, life expectancy at 1 year of age was higher than life expectancy at birth only for the total black population and for black males. In contrast, the last time this was noted for the white population was in the 1969–1971 decennial life tables (8).

Caution must be used in drawing conclusions from the figures in column 7 (e_x). For example, in observing that the average remaining lifetime of white persons is greater than that of black persons, one should not conclude that the oldest ages reached by white persons necessarily exceed those attained by the most long-lived black persons. The difference in average length of life results from the fact that a greater proportion of black people die before reaching old age. For example, the proportion surviving to 75 years of age is greater among white persons (66.0%) than black persons (51.0%); yet, the average length of life remaining at 75 years of age is very similar for the two populations (10.54 years for black persons and 11.15 years for white persons) (Tables 4 and 7).

Results

Life expectancy in the United States

Tables 1–9 show complete life tables by race (white and black) and sex for the period 1999–2001. Life expectancy at birth for 1999–2001 represents the average number of years that a group of infants would live if the infants were to experience throughout life the age-specific death rates prevailing in 1999–2001. In 1999–2001, life expectancy at birth was 76.86 years for the total population, 74.13 years for males, 79.49 years for females, 77.43 years for the total white population, 74.78 years for white males, 79.99 years for white females, 71.81 years for the total black population, 68.17 years for black males, and 75.16 years for black females. In comparison, life expectancy at birth in 1900–1902 was 49.24 years for the total population, 47.88 years for males, 50.70 years for females, 49.64 years for the total white population, 48.23 years for white males, 51.08 years for white females, 33.80 years for the total black population, 32.54 years for black males, and 35.04 years for black females (Table 12).

A sex gap favoring females has existed in all decennial periods since 1900–1902 (Table 12). In 1999–2001, female life expectancy at birth was 5.34 years greater than male life expectancy. In comparison, it was 6.98 years greater in 1989–1991. From 1900–1902 to 1969–1971, the female advantage increased from 2.82 years to 7.60 years. The increasing gap during these years is attributed to increases in male mortality due to ischemic heart disease and lung cancer, both

of which increased largely as the result of men's early and widespread adoption of cigarette smoking (9,10). Since 1969–1971, the gap in favor of females has narrowed from 7.60 years to 5.34 years, reflecting proportionately greater increases in lung cancer mortality for women than for men and proportionately larger decreases in heart disease mortality among men (9,10).

Life expectancy for the white population has been greater than that of the black population in every decade since 1900–1902. At the turn of the last century, life expectancy at birth for the white population was 15.84 years greater than that of the black population. As of 1999–2001, that advantage had narrowed to 5.62 years, a historically record low level. Although the pattern was one of general decline over the past 100 years, the white population advantage did increase at some points, such as between 1979–1981 and 1989–1991. This increase was largely the result of increases in mortality among the black male population due to HIV infection and homicide (9,11).

Among the four race-sex groups in 1999–2001, white females had the highest life expectancy at birth (79.99 years), followed by black females (75.16 years), white males (74.78 years), and black males (68.17 years). Between 1999–2001 and the previous decennial period (1989–1991), life expectancy at birth increased 3.70 years for black males, 2.06 years for white males, 1.43 years for black females, and 0.54 years for white females. Between 1900–1902 and 1999–2001, black females and males experienced the greatest increases in life expectancy at birth (Figure 1). Over the 10 decades, life expectancy increased by 40.12 years for black females (from 35.04 to 75.16 years), 35.63 years for black males (from 32.54 to 68.17 years), 28.91 years for white females (from 51.08 to 79.99 years), and 26.55 years for white males (from 48.23 to 74.78 years).

Examining life expectancy at other ages is also of interest. For example, 65 years of age represents the traditional age at retirement, and 85 years of age represents the age to which, at the turn of the 21st century, 34.5% of the population survived compared with only 6.1% at the turn of the 20th century. On the basis of mortality experienced in 1999–2001, a person aged 65 years could expect to live an average of 17.77 more years for a total of 82.77 years, and a person aged 85 years could expect to live an additional 6.22 years on average for a total of 91.22 years.

Survivorship in the United States

Table 13 shows trends in survivorship from 1900–1902 to 1999–2001. In 1999–2001, 99.3% of all infants born in the United States survived the first year of life. In contrast, only 87.6% of infants born in 1900–1902 survived the first year. Approximately 50.9% of the 1999–2001 life table cohort survived to 80 years of age, and about 1.5% survived to age 100. In contrast, in 1900–1902 only 13.5% survived to 80 years of age, and only 0.03% survived to age 100.

In 1900–1902, race differentials in survival were considerable (Figure 2). Black male and female survival at all ages was substantially lower than white male and female survival. The median age at death for the white population was approximately 60 years of age, compared with a little over 30 years of age for the black population. In other words, whereas one-half of the white population could expect to reach their 60th birthday, one-half of the black population died by about age 30. The differences in survival are particularly noticeable at age 10. For the white population, survival was about 80% at age 10. In contrast, only 63% of the black population survived to age 10. A closer look at survival

Figure 1. Life expectancy at birth by race and sex: Death-registration states, 1900–1902 to 1919–1921, and United States, 1929–1931 to 1999–2001

between birth and 10 years of age for 1900–1902 shows that nearly 25% of the black population died in their first year of life compared with about 12% of the white population (9).

By 1999–2001, black population survival was still lower overall than white population survival (Figure 3). However, the clear separation between the sex-specific survival curves for the white and black populations shown in Figure 2 is no longer apparent. Figure 3 shows that

Figure 2. Percentage surviving by age, race, and sex: Death-registration states, 1900–1902

Figure 3. Percentage surviving by age, race, and sex: United States, 1999–2001

Figure 4. Percentage surviving by age: Death-registration states, 1900–1902, and United States, 1949–1951 and 1999–2001

although black male survival still lags behind the other race-sex groups, black female survival exceeds white male survival at older ages. Black female survival at 60 years of age improved to 84.0% from 27.5% in 1900–1902. At 80 years of age, survival for black females improved from 6.7% in 1900–1902 to 46.4% in 1999–2001. A major reason for improved black population survival over the past 100 years is substantially decreased mortality at younger ages. By 1999–2001, black survival at age 10 years improved from 63.4% in 1900–1902 to 98.3%, which was only about 1% lower than survival for the white population at age 10 years.

Plotting the percentage surviving by age for the periods 1900–1902, 1949–1951, and 1999–2001 shows an increasingly rectangular survival curve (Figure 4). That is, the survival curve has become increasingly flat in response to progressively lower mortality, particularly at the younger ages, and increasingly vertical at the older ages. The survival curve for 1900–1902 shows a rapid decline in survival in the first few years of life and a relatively steady decline thereafter. In contrast, the survival curve for 1999–2001 is nearly flat until about 50 years of age, after which the decline in survival becomes more rapid. Improvements in survival between 1900–1902 and 1949–1951 occurred at all ages, although the largest improvements were among the younger population. Between 1949–1951 and 1999–2001, improvements occurred primarily for the older population.

Table 12. Life expectancy by age, race, and sex: Death registration states, 1900–1902 to 1919–1921, and United States, 1929–1931 to 1999–2001

Spreadsheet version available from: ftp://ftp.cdc.gov/pub/Health_Statistics/NCHS/Publications/NVSR/57_01/Table12.xls.

[Alaska and Hawaii included beginning in 1959. For decennial periods prior to 1929–1931, data are for groups of registration states as follows: 1900–1902 and 1909–1911, 10 states and the District of Columbia; 1919–1921, 34 states and the District of Columbia. Beginning in 1970, data excludes deaths of nonresidents of the United States]

See footnote at end of table.

Table 13. Survivorship by age, race, and sex: Death registration states, 1900–1902 to 1919–1921, and United States, 1929–1931 to 1999–2001—Con.Spreadsheet version available from: ftp://ftp.cdc.gov/pub/Health_Statistics/NCHS/Publications/NVSR/57_01/Table13.xls.

[Alaska and Hawaii included beginning in 1959. For decennial periods prior to 1929–1931, data are for groups of registration states as follows: 1900–1902 and 1909–1911, 10 states and the District of Columbia; 1919–1921, 34 states and the District of Columbia. Beginning in 1970, data excludes deaths of nonresidents of the United States]

Acknowledgments

The authors are grateful to Kirill F. Andreev, Population Division, Department of Economics and Social Affairs, United Nations; Robert Schoen, Department of Sociology, Pennsylvania State University; and John R. Wilmoth, Department of Demography, University of California-Berkeley for their insightful comments and suggestions. We are also grateful to Felicitie C. Bell, Stephen C. Goss, Bert Kestenbaum, Alice H. Wade, and Alvin K. Winters, Office of the Chief Actuary, Social Security Administration, for their helpful suggestions and for providing us with the Medicare data used to produce these life tables. This report was prepared under the general direction of Charles J. Rothwell, Director, Division of Vital Statistics, and Robert N. Anderson, Chief of the Mortality Statistics Branch (MSB). Content review was provided by Betzaida Tejada-Vera of MSB. This report was edited by Megan M. Cox and Demarius V. Miller, CDC/CCHIS/NCHM/Division of Creative Services, Writer-Editor Services Branch, and typeset by Jacqueline M. Davis, CDC/CCHIS/NCHM/Division of Creative Services; graphics were produced by Lisette Baylor, CDC/CCHIS/NCHM/Division of Creative Services, NOVA contractor.
