

# Interactive RadioEpidemiologic Program (IREP) Update

**Timothy D. Taulbee, PhD, CHP**

**Daniel Stancescu, PhD**

*Division of Compensation Analysis and Support (DCAS)*

Advisory Board on Radiation and Worker Health (ABRWH) Meeting  
Augusta, Georgia | August 16, 2023

## Preview of the IREP Update

- Proposing to change Probability of Causation (PC) procedure, not the cancer risk models nor any dose reconstructions
- Update will correct a negative bias in IREP that is observed in some claims thus generally increasing the Probability of Causation
- Update ensures no claims are being incorrectly denied compensation when the Probability of Causation is close to 50%
- Update likely only impacts a few claims (2-4) with a Probability of Causation (PC) greater than 49.5%

# Overview

- Background - Probability of Causation
- Quantile Computation Methods
- Potential Computation Impact on Claims
- IREP Update – New Probability of Causation Procedure
- Expected Programmatic Impact

# Background – Probability of Causation

# Probability of Causation Rule - (42 CFR § 81)

- *Guidelines for Determining the Probability of Causation Under the Energy Employees Occupational Illness Compensation Program Act of 2000; Final Rule*
- Rule promulgates EEOICPA's "at least as likely as not" standard
  - *Is there at least a 50-50 chance that a worker's cancer was caused by occupational radiation exposure (rather than by something else)?*

# Probability of Causation

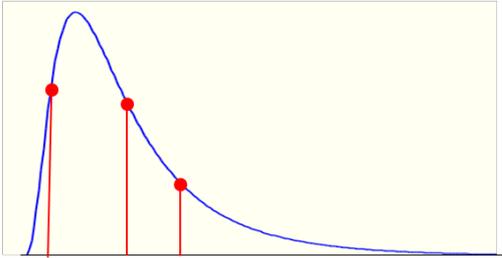

- Frequently abbreviated as “PC” or “PoC,” refers to the proportion of disease in a given population that would not have occurred absent the exposure of interest

$$PC = \frac{RadRisk}{RadRisk + BasRisk}$$

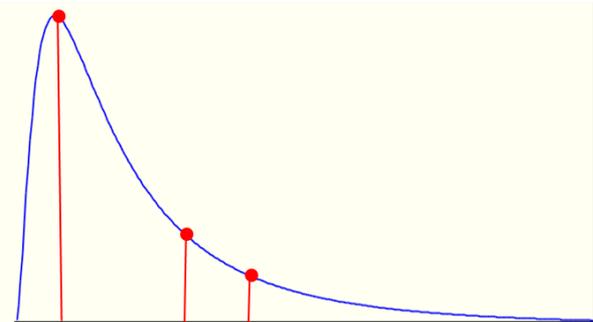

- *RadRisk* = the risk of an individual's cancer due only to occupational radiation exposure
- *BasRisk* = the baseline (background) risk of that cancer

# NIOSH-IREP propagates the uncertainty using Monte Carlo methods to compute the Probability of Causation

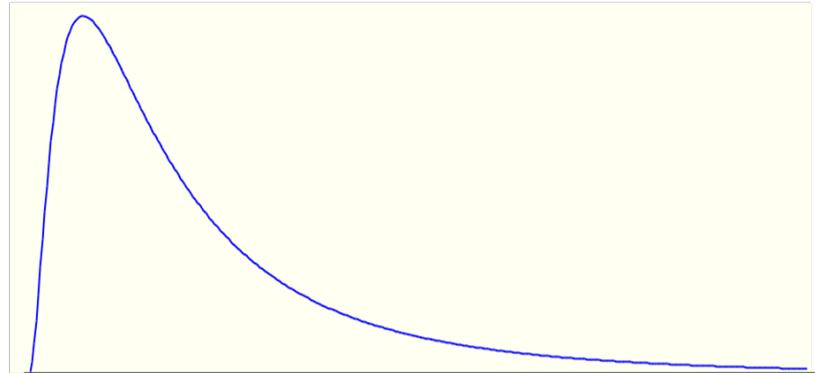

Cancer Risk Model Distribution

Radiation Dose Distribution

PC Distribution

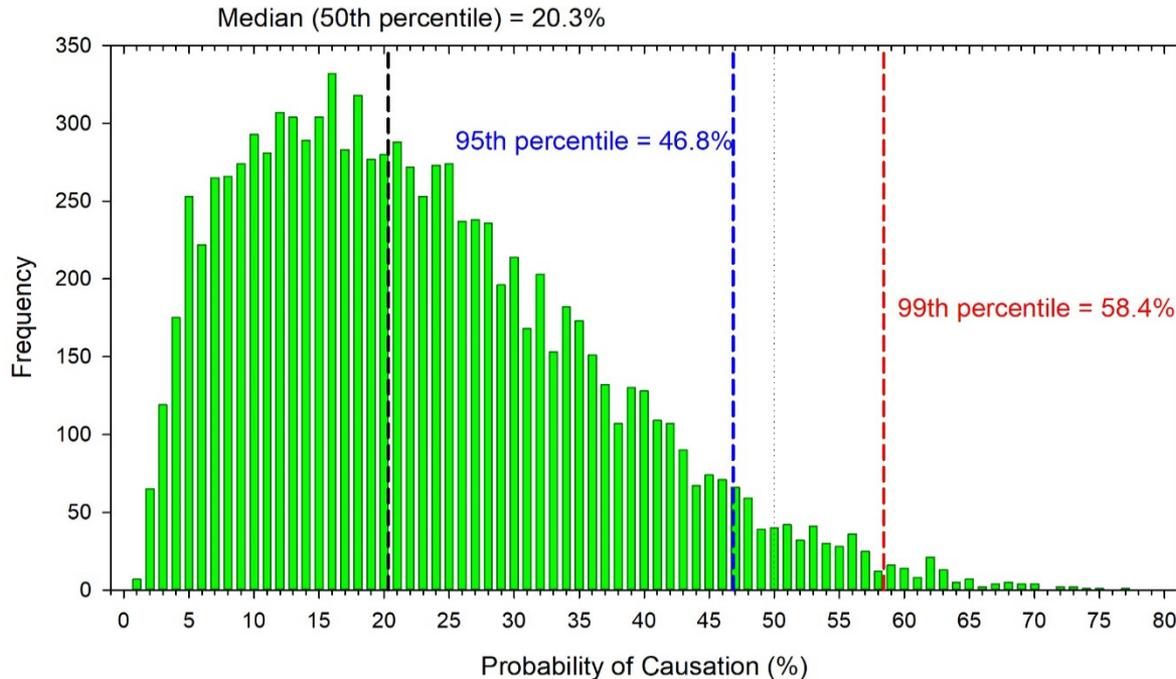

# Probability of Causation Distribution

- EEOICPA requires the calculation of PC, expressed as a percentage (e.g., a PC of 0.5 is expressed as 50%).
- “At least as likely as not” standard means the claim is compensable if  $PC \geq 50\%$  at the upper 99<sup>th</sup> percent confidence interval (credibility limit) of the PC (*42CFR§81.2*)
- Upper 99<sup>th</sup> percentile of PC is calculated within the NIOSH-IREP software program (*42CFR§81.10*)

# Example PC Credibility Limits

- Male, age 20y at first exposure, exposed to 1 rem of photons ( $E > 250$  keV) each year for 30 years. Diagnosed with liver cancer at age 65. ( $n = 10000$  PC simulations)

# Procedure to Update NIOSH-IREP 42CFR§81.12

- NIOSH may periodically revise NIOSH-IREP to
  - *Add, modify, or replace cancer risk models*
  - *Improve modeling uncertainty*
  - *Improve functionality and user interface of NIOSH-IREP*
- NIOSH will submit substantive changes of NIOSH-IREP to the Advisory Board on Radiation and Worker Health (ABRWH) for review and address any recommendations from the Board's review before completing and implementing the change
- NIOSH will also inform the public of proposed changes and address relevant public comments through Federal Register Notices

# Quantile Computation Methods

# Sample Quantile Definitions

- Hyndman and Fan (1996) presented nine sample quantile definitions with a goal of standardization
- Currently there is **No** standard definition of a percentile, however there are multiple definitions currently in use
- Probabilistic modeling and risk analysis software packages such as Crystal Ball, @Risk, Analytica, and Model Risk (Vose) have different methods implemented to compute percentiles
- Statistical Software Packages (SAS and R) have multiple methods available with one method being the default.

# Select Examples of Sample Quantile Definitions

Method	Software	Description
<b>Type 1</b>	<i>Nearest rank method</i>	Inverse of empirical cumulative distribution function
<b>Type 2</b>	SAS (default)	Same as Type 1 but with averaging at discontinuities
<b>Type 3</b>		The Observation numbered closest to $Np$
<b>Type 4</b>	@Risk, Crystal Ball	Linear interpolation of the empirical distribution function (EDF)
<b>Type 5</b>		Piecewise linear function where the knots are the values midway through the steps of the EDF
<b>Type 6</b>	Excel (PERCENTILE.EXC)	Linear interpolation of the expectations of the order statistics for the uniform distribution [0,1]
<b>Type 7</b>	R (default), Analytica (IREP)	Linear interpolation of the modes for the order statistics for the uniform distribution [0,1]

# Comparison of Different Methods

- Sample from a Simple Lognormal Distribution
  - Geometric Mean (GM)= 3
  - Geometric Standard Deviation (GSD) = 6
  - **Theoretical 99% = 193.808**
  - RLH: Random Latin Hypercube
  - MLH: Median Latin Hypercube

# Method Comparison with Increasing Sample Size (1 of 2)

$X \sim \text{LN}(3,6)$ , sampled using the MLH and RLH methods

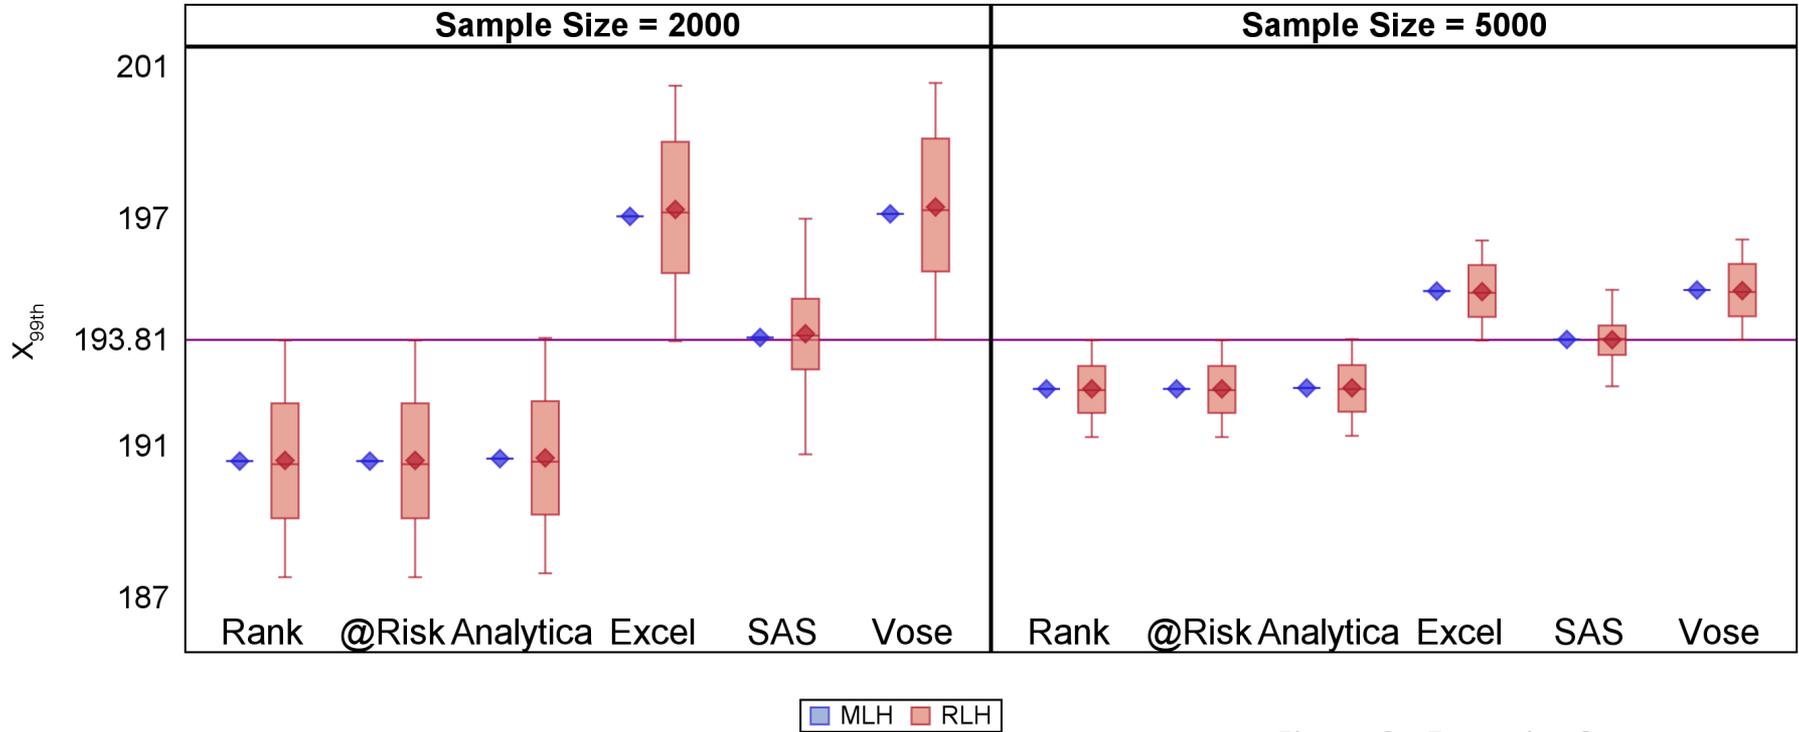

Figure 2: Executive Summary

# Method Comparison with Increasing Sample Size (2 of 2)

$X \sim \text{LN}(3,6)$ , sampled using the MLH and RLH methods

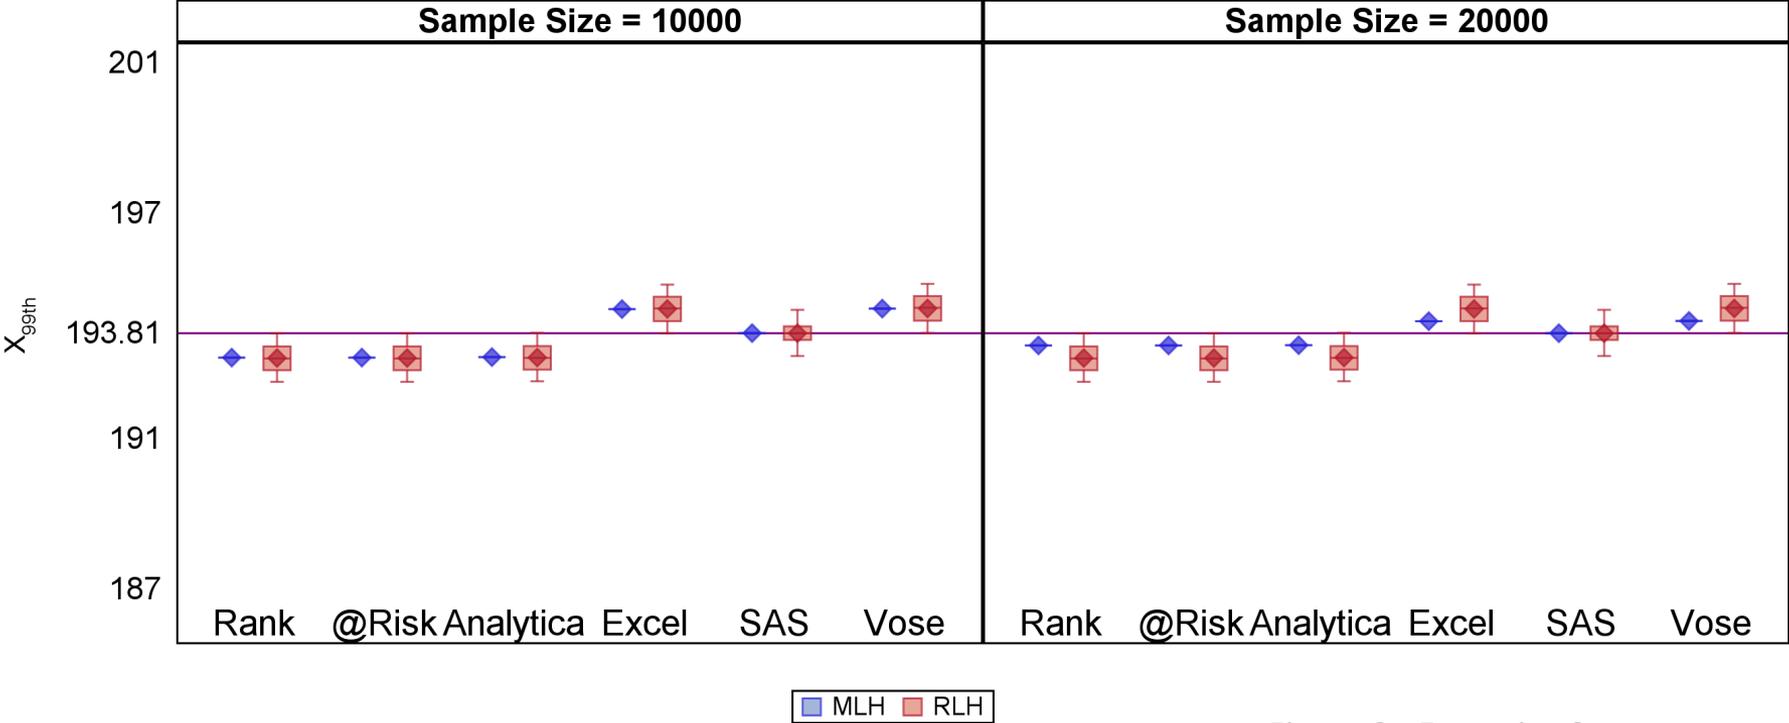

Figure 2: Executive Summary

# Convergence as the sample size increases

Relative Bias (RB) by sample size and percentile definition, for the 99-th percentile of LN(3,6) distribution, and RLH sampling

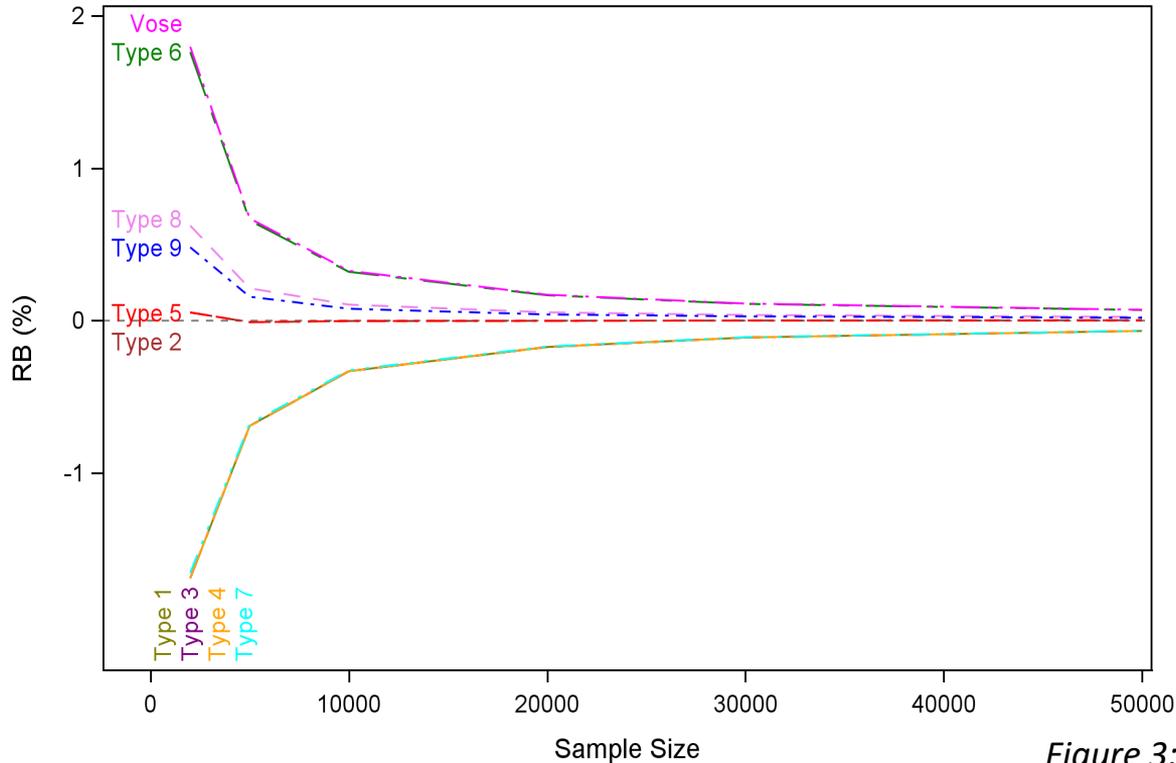

Figure 3: Executive Summary 17

# Summary of Method Evaluation

- At low number of iterations (small sample size), relative bias can be 1% to 2% for individual distributions
- Type 2 (SAS) appears to be least impacted by sample size
- Type 4 (@Risk) and Type 7 (Analytica-IREP) appear to have a negative bias at small sample sizes
- Type 6 (Excel) and VOSE appear to have a positive bias at small sample sizes
- All methods converge to the same value as sample size increases

# Potential Computational Impact on Claims

# Potential Impact on Claims

- IREP uses the Analytica statistical engine and can result in a negative bias at the 99<sup>th</sup> percentile
- The bias is more pronounced when:
  - Large dose uncertainty
    - Dose distribution has a large Geometric Standard Deviation (GSD)
  - Large number of IREP input exposures
- These can translate into a Probability of Causation (PC) distribution with a longer tail with larger distance between PC realizations

# PC Number of Iterations

- PC @ 99<sup>th</sup> %
  - $n=2000$ ,  $PC = 50.41\%$
  - $n=10000$ ,  $PC = 49.66\%$
  - $n=20000$ ,  $PC = 49.81\%$
  - $n=30000$ ,  $PC = 49.99\%$
- Overall goal is to improve the modeling uncertainty at the 99<sup>th</sup> percentile of the PC

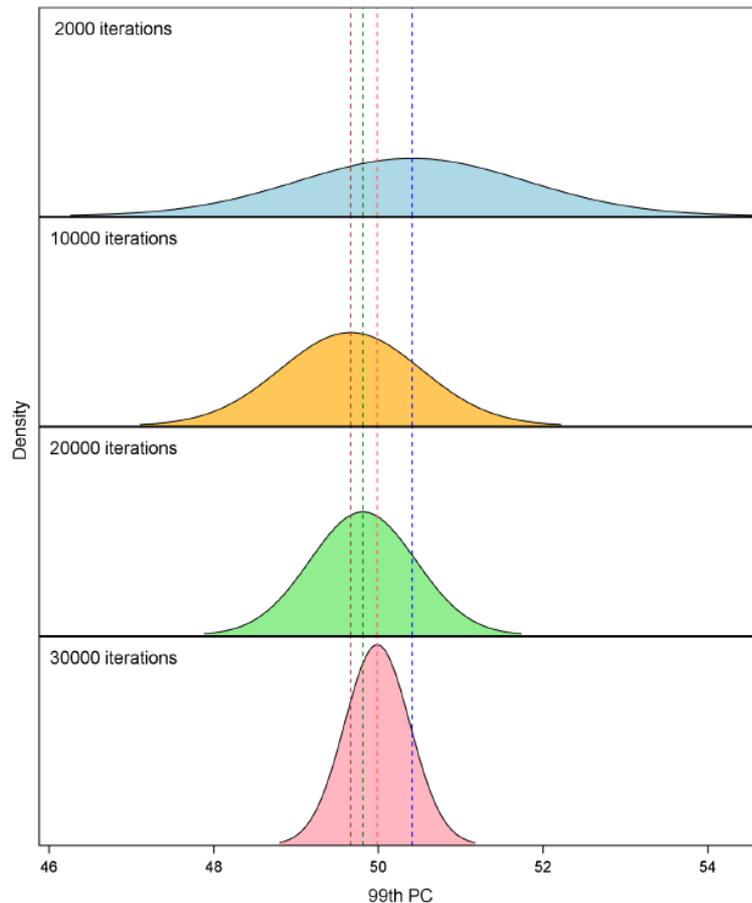

Figure 12: Executive Summary 21

# Current Methodology – 30 runs at 10,000 iterations

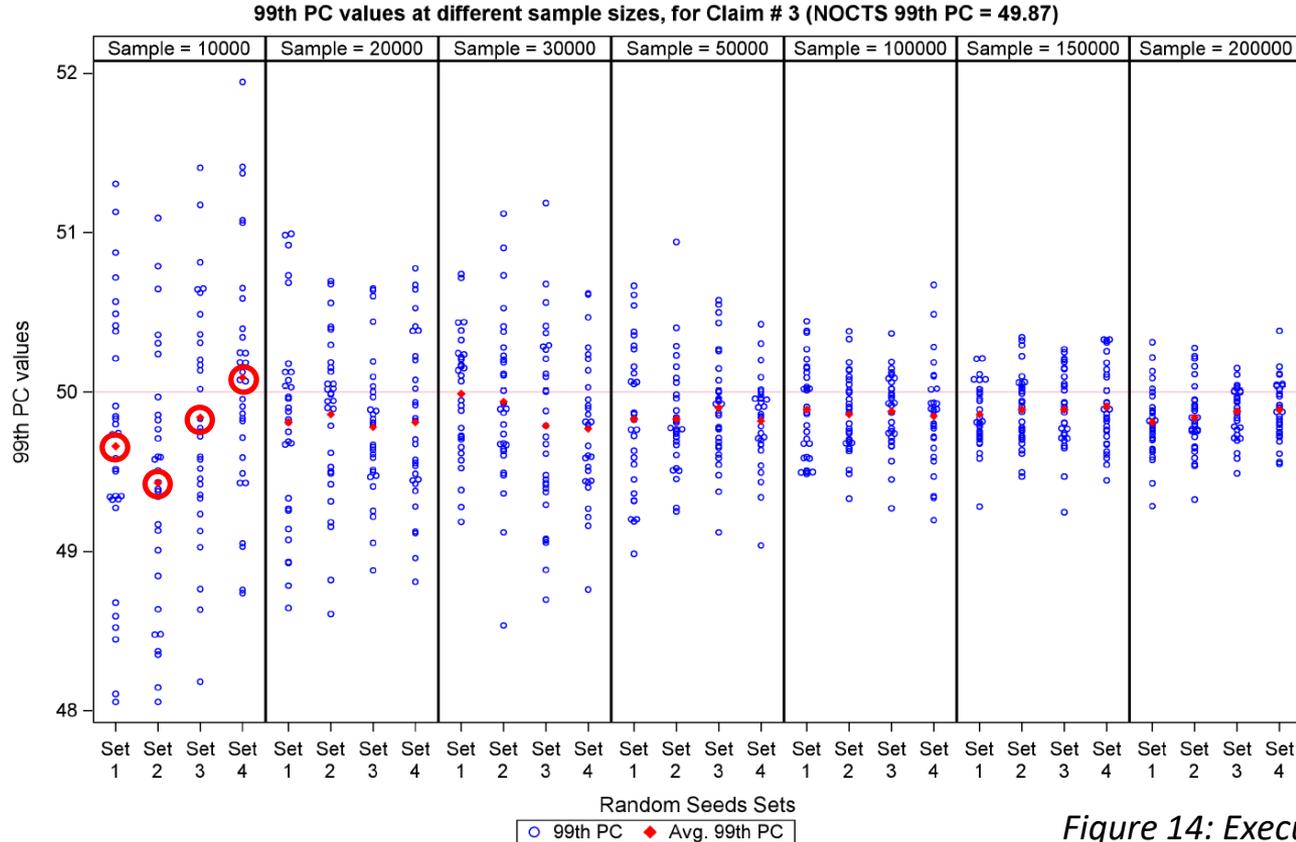

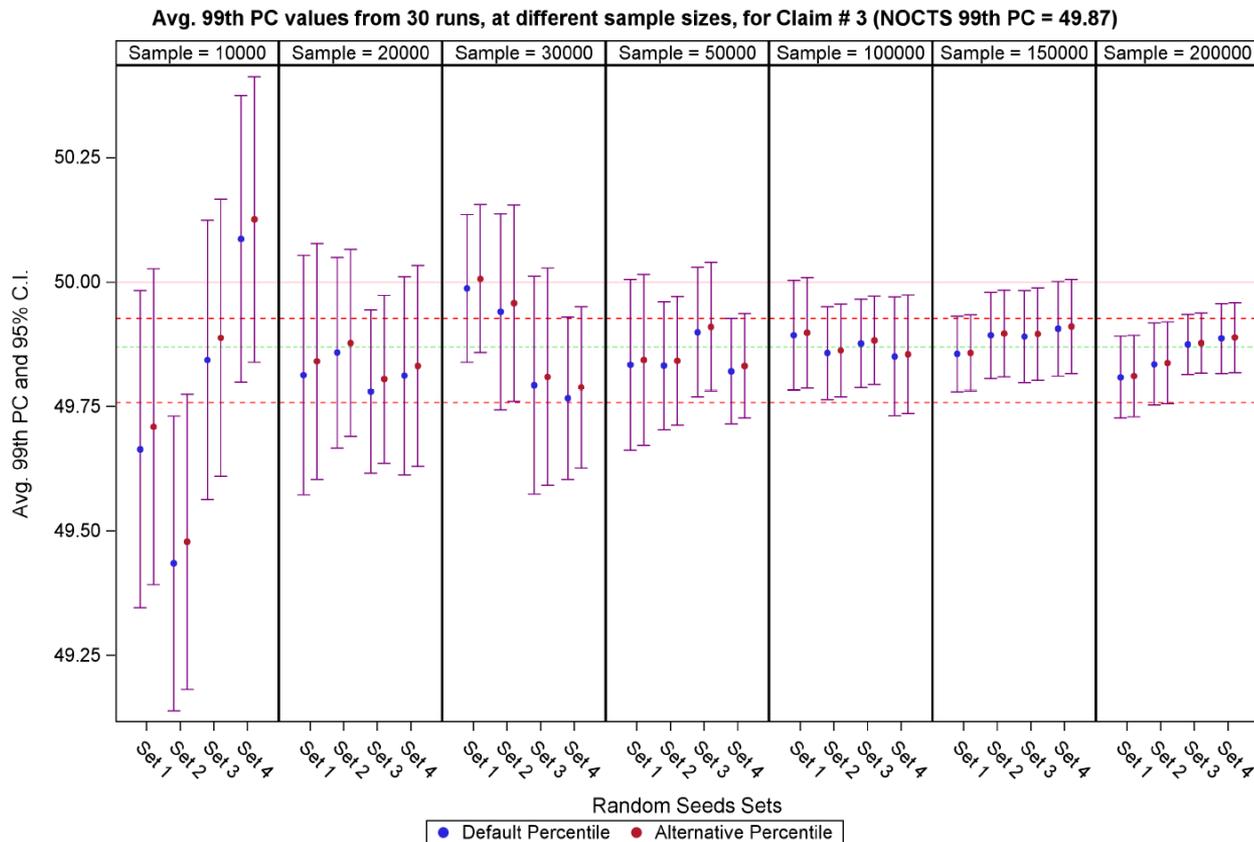

Figure 14: Executive Summary 22

# Current Methodology – Confidence Interval

95% C.I. for the 99th PC value is based on a sample size of 5,000,000

Figure 15: Executive Summary 23

**IREP Update – Change to PC Procedure**

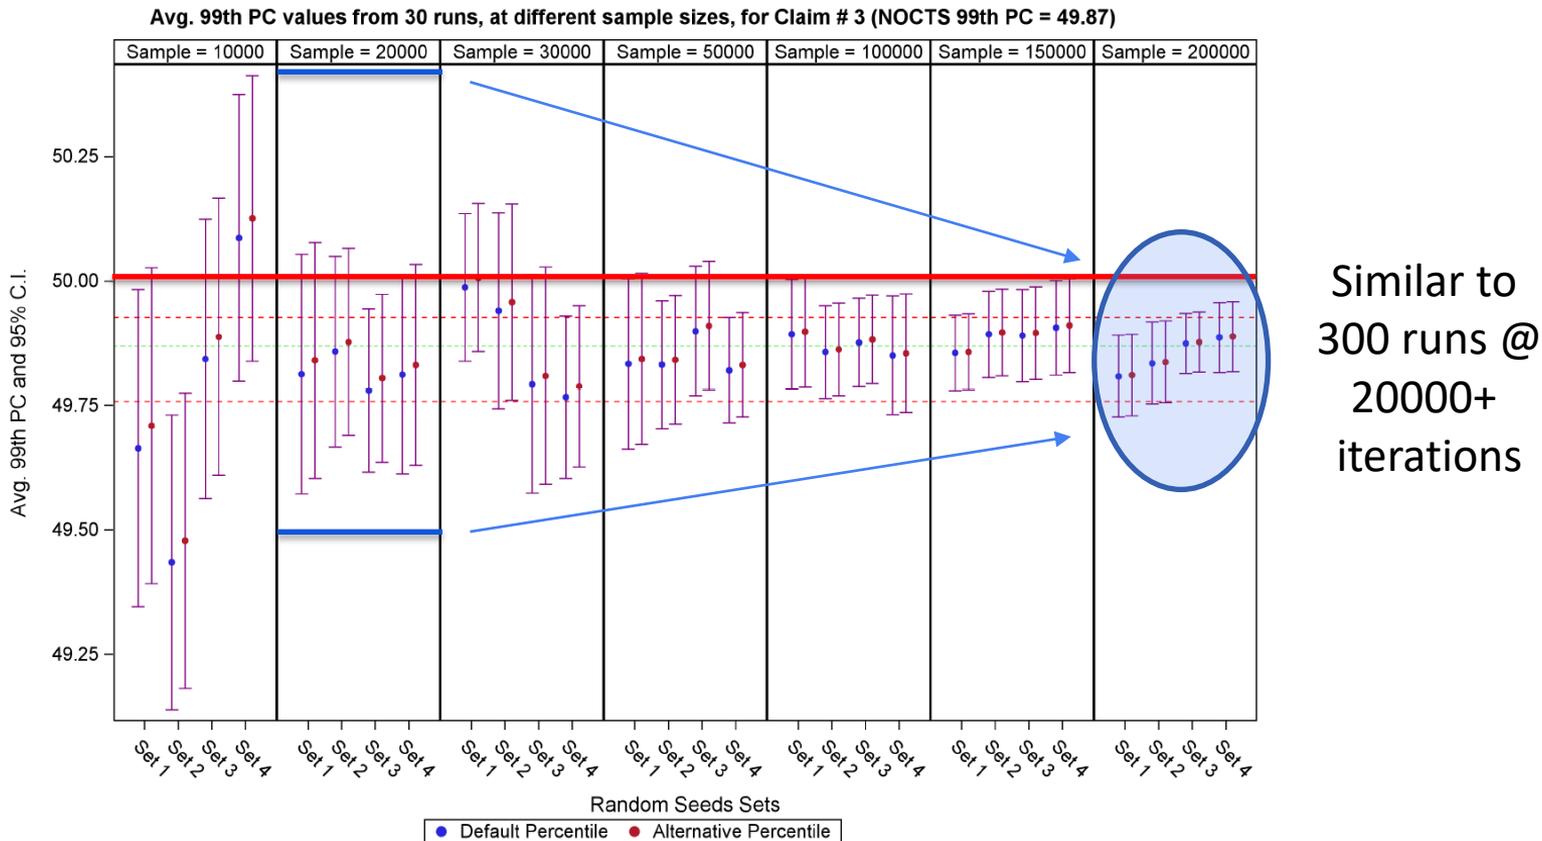

# IREP Update Changes (version 6.0)

- Current IREP (v5.9)
  - Maximum number of iterations is 10,000
- **New IREP (v6.0)**
  - Maximum number of iterations is 20,000
- Current IREP\_EE (v5.9)
  - Averages 30 runs at 10,000 iterations for final PC
- **New IREP\_EE (v6.0)**
  - Capability for either 30 or 300 runs at 20,000+ iterations

# Proposed Probability of Causation (PC) Procedure

PC Value	IREP Version	Current Procedure (# of Iterations)	Proposed Procedure (# of Iterations)
<b>&lt;45% or &gt; 52%</b>	IREP	2,000	20,000
<b>45% to 52%</b>	IREP-EE	30 runs @ 10,000	30 runs @ 20,000
<b>49.5% to 50.5%</b>	IREP-EE	30 runs @ 10,000	300 runs @ optimal # of iterations (20,000 – 70,000+)

# Improving the Modeling Uncertainty

95% C.I. for the 99th PC value is based on a sample size of 5,000,000

Figure 15: Executive Summary 27

## IREP Predictive Tool for Claims 49.5% to 50.5% PC

- New tool that evaluates the width of the confidence interval (CI) based on the claim uncertainty distributions
- IREP Predictive Tool will be run by NIOSH/ORAU to determine the optimal number of iterations
- The tool rapidly conducts 300 runs using only 1,000 iterations and then applies a power function to predict the optimal number of iterations in order to achieve a CI of less than 0.1
- Final PC will be the average of 300 runs at the optimal number of iterations

**Expected Programmatic Impact**

## Expected Programmatic Impacts

- Overall IREP 6.0 should have minimal programmatic impact
- Greater precision in the PC value will be achieved
- Probability of Causation run times will increase as the number of iterations increases (computer power changes over time)
- Slightly more complicated evaluation process when the PC value is near the 50% (49.5% to 50.5%)
- Additional computational time increase will be minimized with the use of the IREP Predictive Tool to optimize number of iterations

## Program Evaluation Report (PER) (1 of 2)

- All PC calculations for claims between 45% to <50% will be re-evaluated using the new PC procedure
- Minimal impact on claims in this region as we have been using 30 runs at 10,000 iterations for many years (since 2006)
- Relatively few claims with PC's in the 49.5% to 50.5% range
- **PRELIMINARY** Evaluation of using 2019 data is that 2-4 claims may exceed 50% PC
- Considering programmatically over 50,000+ claims evaluated to date 2-4 claims is approximately 0.008%

## Program Evaluation Report (PER) (2 of 2)

- PER will be initiated once we implement IREP 6.0; however, this will take some time due to current IT constraints
  - (i.e. require contractor to querying claims and current inability to batch process IREP claims)
- Dose Reconstructions do not have to be redone; this is purely a PC calculation of already completed Dose Reconstructions
- Subcommittee on Procedure Review (SPR) will likely review the PER when it is completed
- Target implementation is September 2023

# Summary

- Proposing to change Probability of Causation procedure, not the cancer risk models nor any dose reconstructions
- Increasing the number of iterations in IREP will correct a negative bias in IREP observed with some claims thus generally increasing the Probability of Causation
- Increasing the number of iterations also improves the modeling uncertainty by decreasing the width of the Confidence Interval (CI), thus ensuring that claims close to 50% will be properly evaluated
